Many people with AIDS are affected by a wasting syndrome that is known, especially in Africa, as “slim disease”. It involves chronic diarrhoea and severe weight loss. Another condition, seen worldwide, is AIDS encephalopathy or AIDS dementia, which is caused by HIV crossing “blood–brain barrier”. In its late stages, AIDS encephalopathy resembles senile dementia or Alzheimer’s disease. AIDS dementia appears to result not from opportunistic infection, but from the action of the virus itself.

TUBERCULOSIS. An alarming factor in the AIDS epidemic is the increasing link between HIV infection and tuberculosis. In countries where tuberculosis is endemic, many people are infected in childhood. When the immune system breaks down, as in HIV infection, tuberculosis becomes active and the person becomes contagious to others. Studies in Rwanda, the USA, Zaire and Zambia found that HIV-positive individuals were 30–50 times more likely to develop active tuberculosis than HIV-negative people. As a consequence, AIDS is reviving an old problem in developed countries e.g. in the USA, where there was a sudden increase in tuberculosis cases. The situation in developing countries is still worst.

Drug therapy should be individualized. Patients with multi drug resistance should receive at least three drugs to which their organism is sensitive (20).

PERSISTENT GENERALIZED LYMPHADENOPATHY
Lymph nodes are larger than one centimetre in diameter, in two or more sites other than the groin area for a period of at least three months.

KAPOSI SARCOMA. A tumour featuring reddish brown or purplish plaques or nodules on the skin and mucous membranes. Endemic in Africa prior to HIV. It used to affect mainly older men. With HIV infection it affects a wider age range and both sexes, and is characterized by lesions in the mouth or gut; or lesions are generalized (in two or more places) or rapidly progressive or invasive.

OROPHARYNGEAL CANDIDIASIS. Caused by a common yeast fungus, oral thrush presents with soreness and redness, with white plaques on the tongue, and in the mouth and throat; and sometimes a white fibrous layer covering the tonsils and back of the mouth. Infection of the oesophagus presents with pain behind the breastbone.

CYTOMEGALOVIRUS RETINITIS. Inflammation of the eye retina which may lead to blindness.

PNEUMOCYSTOSIS CARINII PNEUMONIA. Symptoms can include a dry, non-productive cough; inability to take a full breath and occasional pain on breathing; and weight loss and fever.

TOXOPLASMA ENCEPHALITIS. Protozoal infection in the central nervous system, presenting with focal neurological signs such as mild hemiplegia or stroke, resulting from damage to part of the brain, seizures or altered mental status.

HAIRY LEUKOPLAKIA. White patches on the sides of the tongue, in vertical folds resembling corrugations.

CRYPTOCOCCAL MENINGITIS. A fungal infection in the central nervous system which usually presents with fever, headache, vomiting and neck stiffness.

HERPES-ZOSTER OR SHINGLES. Viral inflammation of the central nervous system, presenting with localised pain and burning sensations, followed by vesicle eruption (skin blistering) and ulceration.

SEVERE PRURIGO OR PRURITIC DERMATITIS, Chronic skin inflammation in the form of a very itchy rash of small flat spots developing into blisters.

SEVERE OR RECURRENT SKIN INFECTIONS, Warts; dermatophytosis or ringworm; and folliculitis (inflammation of hair follicles).

DIAGNOSIS OF AIDS

CLINICAL

I. WHO case definition for AIDS surveillance
For the purposes of AIDS surveillance an adult or adolescent (> 12 years of age) is considered to have AIDS if at least 2 of the following major signs are present in combination with at least 1 of the minor signs listed below, and if these signs are not known to be due to a condition unrelated to HIV infection (21).
The clinical definition is relatively specific (if used correctly), meaning that the vast majority of people diagnosed as having AIDS will have been correctly assessed. However, studies show that the definition is relatively insensitive, meaning that only half the patients who have severe illness related to HIV infection are included. This is because not all HIV-related opportunistic diseases are included in the AIDS definition. Tuberculosis is widely recognized as the commonest opportunistic disease associated with HIV in Africa. But because TB causes wasting, cough and fever in most patients, the AIDS clinical case definition cannot reliably distinguish between HIV-positive and HIV-negative TB patients.

The clinical case definition was developed to enable reporting of the number of people with AIDS for surveillance purposes. However, for the purpose of individual case management, it is useful to be able to diagnose whether illnesses may be related to HIV infection (symptomatic HIV infection) because:

- clinical manifestations can be a reliable indicator of underlying HIV infection;
- over-use of HIV testing is avoided, testing is used to confirm suspected HIV infection, rather than as a diagnostic tool in the first instance;
- a patient with suspected HIV infection can be counselled about having an HIV test, the implications for them and their sexual partners, self-care and nutrition;
- many HIV-related illnesses can be treated, improving the patient’s quality of life;
- certain drugs (such as thiacetazone) cause severe side effects in people with HIV infection, and should not be prescribed for them.

**Children (22)**

The case definition for AIDS is fulfilled if at least 2 major signs and 2 minor signs are present (if there is no other known cause of immunosuppression).

## Major signs
- weight loss ≥ 10% of body weight
- chronic diarrhoea for more than 1 month
- prolonged fever for more than 1 month (intermittent or constant).

## Minor signs
- persistent cough for more than 1 month
- generalized pruritic dermatitis
- history of herpes zoster
- oropharyngeal candidiasis
- chronic progressive or disseminated herpes simplex infection
- generalized lymphadenopathy.

The presence of either generalized Kaposi sarcoma or cryptococcal meningitis is sufficient for the diagnosis of AIDS.

The clinical definition is relatively specific (if used correctly), meaning that the vast majority of people diagnosed as having AIDS will have been correctly assessed. However, studies show that the definition is relatively insensitive, meaning that only half the patients who have severe illness related to HIV infection are included. This is because not all HIV-related opportunistic diseases are included in the AIDS definition. Tuberculosis is widely recognized as the commonest opportunistic disease associated with HIV in Africa. But because TB causes wasting, cough and fever in most patients, the AIDS clinical case definition cannot reliably distinguish between HIV-positive and HIV-negative TB patients.

The clinical case definition was developed to enable reporting of the number of people with AIDS for surveillance purposes. However, for the purpose of individual case management, it is useful to be able to diagnose whether illnesses may be related to HIV infection (symptomatic HIV infection) because:

- clinical manifestations can be a reliable indicator of underlying HIV infection;
- over-use of HIV testing is avoided, testing is used to confirm suspected HIV infection, rather than as a diagnostic tool in the first instance;
- a patient with suspected HIV infection can be counselled about having an HIV test, the implications for them and their sexual partners, self-care and nutrition;
- many HIV-related illnesses can be treated, improving the patient’s quality of life;
- certain drugs (such as thiacetazone) cause severe side effects in people with HIV infection, and should not be prescribed for them.

**Children (22)**

The case definition for AIDS is fulfilled if at least 2 major signs and 2 minor signs are present (if there is no other known cause of immunosuppression).

**LABORATORY DIAGNOSIS**

**SCREENING TESTS:** As antibodies to HIV are far easier to detect than the virus itself, their presence or absence in blood-stream is the basis for the most widely used test of HIV infection. A person whose blood contains HIV antibodies is said to be HIV-positive, or seropositive, meaning that he or she is infected with HIV. There is now a wide range of screening tests based on detection of HIV-antibodies. To be reliable, a screening test must be **sensitive** enough to identify all "true positives", while being **specific** enough to record few "false positives". The ideal test needs both the attributes.

At present, two different tests are commonly applied. At first a sensitive test is used to detect the HIV-antibodies, while a second confirmatory test is used to weed out any false positive results. The first kind of test is normally the ELISA. The confirmatory test, usually a Western Blot is a highly specific test; it is based on detecting specific antibody to viral core protein (p24) and envelope glycoprotein (gp 41). This is a more difficult test to perform and requires trained and experienced laboratory workers to interpret the test.

**VIRUS ISOLATION:** A test for the virus itself would eliminate the painful uncertainty of AIDS infection. HIV can be recovered from cultured lymphocytes (23). This type of testing is expensive and requires extensive laboratory support.

The current trend in HIV-antibody tests is towards simple, cheap, reliable kits whose results can be read on the spot without much waiting and without the need for laboratory backup. HIV self testing kits are available in the market.

Non-specific laboratory findings with HIV infection may include anaemia, leukopenia (particularly lymphocytopenia) and thrombocytopenia in any combination, polyclonal hypergammaglobulinaemia. Cutaneous infection is frequent early in the course, and becomes universal as the disease progresses (20).

Several laboratory markers are available to provide prognostic information and guide therapy decisions. The most widely used marker is the absolute CD4 lymphocyte count. As the count decreases, the risk of opportunistic infection increases. People with healthy immune system usually have more than 950 CD4 cells/µl of blood. The number falls over the course of HIV infection. People with AIDS usually have CD4 cell count below 200 (USA makes
CD cell count below 200 in an HIV-infected person a definition of AIDS). The trend of the count is much more important than any single reading. The frequency of performance of counts depends on the patient's health system. Some studies suggest that the percentage of CD4 lymphocytes is more reliable indicator of prognosis than the absolute count because the percentage does not depend on calculating a manual differential. Risk of progression to AIDS is high with percentage of CD4 lymphocyte less than 20 (20).

The laboratory tests and their significance are as summarized in Table 3.

### TABLE 3

**Laboratory findings with HIV infection**

<table>
<thead>
<tr>

Source: (20)

The WHO has pointed out the danger of compulsory testing programmes in their tendency to social rejection of HIV-carrier and the resulting social and psychological consequences. Diagnostic testing may be useful in gauging the magnitude and course of the epidemic. It is a gateway to HIV prevention, treatment, care and other support services, including pre-test information and post-test counseling. The WHO five C’s – consent, confidentiality, counselling, correct test results and connection to care and treatment – are principles that apply to all models of HIV testing services and in all circumstances.

**Control of AIDS**

There are four basic approaches to the control of AIDS:

1. **Prevention**

   **(a) EDUCATION**

   Until a vaccine or cure for AIDS is found, the only means at present available is health education to enable people to make life-saving choices (e.g., avoiding indiscriminate sex, using condoms). There is, however, no guarantee that the use of condoms will give full protection. One should also avoid the use of shared razors and toothbrushes. Intravenous drug users should be informed that the sharing of needles and syringes involves special risk. Women suffering from AIDS or who are at high risk of infection should avoid becoming pregnant, since infection can be transmitted to the unborn or newborn. Educational material and guidelines for prevention should be made widely available. All mass media channels should be involved in educating the people on AIDS, its nature, transmission and prevention; this includes international travellers.

   **(b) COMBINATION HIV PREVENTION (24)**

   Combination prevention programmes use a mix of biomedical, behavioural and structural interventions to meet the current HIV prevention needs of particular individuals and communities so as to have the greatest possible impact on reducing new infections.

   ARV drugs play a key role in HIV prevention. People taking ART who achieve optimal viral suppression are extremely unlikely to pass HIV to sexual partners, ARV drugs taken by people without HIV as PrEP or PEP are highly effective in preventing HIV acquisition.

   Other biomedical interventions that reduce HIV risk practices and/or the probability of HIV transmission per contact event include the following:

   - **Male and female condoms and condom compatible lubricant**: male condoms are estimated to reduce heterosexual transmission by at least 80% and to offer 64% protection in anal sex among men who have sex with men, if used consistently and correctly. Fewer data are available for the efficacy of female condoms, but evidence suggests they can have a similar prevention effect.
   - **Needle and syringe programmes** are highly associated with a reduction in HIV transmission through injecting drug use.
   - **Opioid substitution therapy** with methadone or buprenorphine is the most effective form of treatment for opioid dependence and has the additional benefit of effectively reducing HIV risk behaviour and transmission through injecting drug use. Opioid substitution therapy also provides adherence support to people on ART.
   - **Voluntary medical male circumcision (VMMC)**: three randomized clinical trials in Africa demonstrated an approximately 60% reduction in the risk of female-to-male sexual transmission. For high-burden settings, joint programme of WHO and United Nations on HIV/AIDS (UNAIDS) recommended the inclusion of VMMC as an additional important strategy for prevention of heterosexually acquired HIV infection in men.

   **(c) PREVENTION OF BLOOD-BORNE HIV TRANSMISSION**

   People in high-risk groups should be urged to refrain from donating blood, body organs, sperm or other tissues. All blood should be screened for HIV 1 & HIV 2 before transfusion. Transmission of infection to haemophiliacs can
be reduced by introducing heat treatment of factors VIII and IX. Strict sterilization practices should be ensured in hospitals and clinics. Pre-sterilized disposable syringes and needles should be used as far as possible. One should avoid injections unless they are absolutely necessary.

2. Antiretroviral treatment

At present there is no vaccine or cure for treatment of HIV infection/AIDS. However, the development of drugs that suppress the HIV infection itself rather than its complications has been important development. These antiviral chemotherapy have proved to be useful in prolonging the life of severely ill patients.

The availability of agents in combination suppress HIV replication. It has a profound impact on the natural history of HIV infection. Patients who achieve excellent suppression of HIV generally have stabilization or improvement of their clinical course which results from partial immunologic reconstitution and a subsequent decrease in complications of immunosuppression. Concept about the timing of such therapy have changed considerably.

Classification of drugs used for ART (20)

The drugs used for ART are classified as:

<table>
<thead>
<tr>
<th>Nucleoside reverse transcriptase inhibitors (NRTIs)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Abacavir (ABC)</td>
</tr>
<tr>
<td>Didanosine (ddi)</td>
</tr>
<tr>
<td>Emtricitabine (FTC)</td>
</tr>
<tr>
<td>Lamivudine (3TC)</td>
</tr>
<tr>
<td>Stavudine (d4T)</td>
</tr>
<tr>
<td>Zidovudine (AZT)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Nucleotide reverse transcriptase inhibitors (NtRTIs)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tenofovir (TDF)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Non-nucleoside reverse transcriptase inhibitors (NNRTIs)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Efavirenz (EFV)</td>
</tr>
<tr>

</tr>
<tr>
<td>Indinavir + ritonavir (IDV/r)</td>
</tr>
<tr>
<td>Lopinavir/ritonavir (LPV/r)</td>
</tr>
<tr>
<td>Saquinavir + ritonavir (SQV/r)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Integrase strand transfer inhibitors (INSTIs)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Raltegravir (RAL)</td>
</tr>
</tbody>
</table>

WHO recommended ARV treatment schedule (2016) (24)

WHO has been providing guidance on the use of ARV drugs since 2002, producing a range of guidelines on various aspects of HIV diagnosis, treatment, and care. The 2016 guidelines aim to combine and harmonize new and existing recommendations, including updated recommendations from the 2013 guidelines on ART for adults, adolescents and children, and ARV treatment and prophylaxis for pregnant and breastfeeding women living with HIV. They also include existing WHO guidance on HIV testing and counselling, HIV prevention, general care for people living with HIV, managing common infections and other comorbidities and monitoring and managing drug toxicities.

The 2016 guidelines are based on a public health approach to further expanding the use of ARV drugs for HIV treatment and prevention, with a particular focus on resource-limited settings. The new clinical recommendations are as follows:

1. WHEN TO START ART

<table>
<thead>
<tr>
<th>When to start ART in adults (&gt; 19 years old)</th>
<th>ART should be initiated in all adults living with HIV, regardless of WHO clinical stage and at any CD4 cell count</th>
</tr>
</thead>
<tbody>
<tr>
<td>As a priority, ART should be initiated in all adults with severe or advanced HIV clinical disease (WHO clinical stage 3 or 4) and adults with a CD4 count ≤ 350 cells/mm³.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>When to start ART in pregnant and breastfeeding women</th>
<th>ART should be initiated in all pregnant and breastfeeding women living with HIV, regardless of WHO clinical stage and at any CD4 cell count and continued lifelong</th>
</tr>
</thead>
<tbody>
<tr>
<td>As a priority, ART should be initiated in all adolescents living with HIV, regardless of WHO clinical stage and at any CD4 cell count (conditional recommendation).</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>When to start ART in children younger than 10 years of age</th>
<th>ART should be initiated in all children living with HIV, regardless of WHO clinical stage or at any CD4 cell count:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Infants diagnosed in the first year of life</td>
<td></td>
</tr>
<tr>
<td>Children living with HIV 1 year old to less than 10 years old (conditional recommendation)</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>When to start ART in children living with HIV, regardless of WHO clinical stage or at any CD4 cell count</th>
<th>ART should be started in all TB patients living with HIV regardless of CD4 count. TB treatment should be initiated first, followed by ART as soon as possible within the first 8 weeks of treatment</th>
</tr>
</thead>
<tbody>
<tr>
<td>HIV-positive TB patients with profound immunosuppression (e.g. CD4 counts less than 50 cells/mm³) should receive ART within the first two weeks of initiating TB treatment</td>
<td></td>
</tr>
</tbody>
</table>

The implementation of recommendation on universal eligibility for ART will mean that more people will start ART earlier. The new recommendation is to provide lifelong ART to all children, adolescents, and adults including all pregnant and lactating women living with HIV, regardless of CD4 cell count. WHO has also expanded earlier recommendation to offer pre-exposure prophylaxis to selected people at substantial risk of acquiring HIV (24).
2. WHAT TO START (2016)

First-line ART in treatment

<table>
<thead>
<tr>
<th>First-line ART for adults</th>
<th>First-line ART for adolescents</th>
<th>First-line ART for children aged 3 to 10 years of age</th>
<th>First-line ART for children younger than 3 years of age</th>
</tr>
</thead>
<tbody>
<tr>
<td>NRTIs plus a non- nucleoside reverse transcriptase inhibitor (NRTI) or an Integrase inhibitor (INSTI) :</td>
<td>NRTIs plus a non- nucleoside reverse transcriptase inhibitor (NRTI) or an Integrase inhibitor (INSTI) :</td>
<td>NRTIs plus a non- nucleoside reverse transcriptase inhibitor (NRTI) or an Integrase inhibitor (INSTI) :</td>
<td>NRTIs plus a non- nucleoside reverse transcriptase inhibitor (NRTI) or an Integrase inhibitor (INSTI) :</td>
</tr>
<tr>
<td>- TDF + 3TC (or FTC) + EFV as a fixed-dose combination is recommended as the preferred option to initiate ART.</td>
<td>- TDF + 3TC (or FTC) + DTG or TDF + 3TC (or FTC) + EFV 400 mg/day may be used as alternative option to initiate ART.</td>
<td>- TDF + 3TC (or FTC) + EFV 400 mg/day may be used as alternative option to initiate ART.</td>
<td>- TDF + 3TC (or FTC) + EFV 400 mg/day may be used as alternative option to initiate ART.</td>
</tr>
<tr>
<td>- If TDF + 3TC (or FTC) + EFV is contraindicated or not available, one of the following alternative options is recommended:</td>
<td>- AZT + 3TC + EFV</td>
<td>- AZT + 3TC + EFV</td>
<td>- AZT + 3TC + EFV</td>
</tr>
<tr>
<td>- AZT + 3TC + NVP</td>
<td>- TDF + 3TC (or FTC) + NVP</td>
<td>- TDF + 3TC (or FTC) + NVP</td>
<td>- TDF + 3TC (or FTC) + NVP</td>
</tr>
<tr>
<td>- TDF + 3TC (or FTC) + NVP</td>
<td>- AZT + 3TC + NVP</td>
<td>- AZT + 3TC + NVP</td>
<td>- AZT + 3TC + NVP</td>
</tr>
<tr>
<td>- TDF + 3TC (or FTC) + DTG or TDF + 3TC (or FTC) + EFV</td>
<td>- TDF + 3TC (or FTC) + EFV</td>
<td>- TDF + 3TC (or FTC) + EFV</td>
<td>- TDF + 3TC (or FTC) + EFV</td>
</tr>
</tbody>
</table>

Countries should discontinue d4T use in first-line regimens because of its well recognized metabolic toxicities.

Fixed-dose combinations

Fixed dose combinations and once-daily regimens are preferred for antiretroviral therapy.

First-line ART for adolescents should consist of two NRTIs plus an NNRTI or an INSTI

For children 3 years and older, EFV is the preferred NNRTI for first-line treatment and NVP is the preferred alternative.

For children 3 to less than 10 years of age, the NRTI backbone should be one of the following, in preferential order:

- ABC + 3TC + EFV
- ABC + 3TC + NVP
- AZT + 3TC + EFV
- AZT + 3TC + NVP
- TDF + 3TC (or FTC) + NVP

For children 3 years and older, the NRTI backbone in second-line treatment and NVP is the preferred alternative.

Infant prophylaxis

Infants born to mothers with HIV who are at high risk of acquiring HIV should receive dual prophylaxis with AZT (twice daily) and NVP (once daily) for the first 6 weeks of life, whether they are breastfed or formula fed.

Breastfed infants who are at high risk of acquiring HIV, including those first identified as exposed to HIV during the puerperal period, should continue infant prophylaxis for an additional 6 weeks (total of 12 weeks of infant prophylaxis) using either AZT (twice daily) and NVP (once daily) or NVP alone.

Infants of mothers who are receiving ART and are breastfeeding should receive 6 weeks of infant prophylaxis with daily NVP. II infants are receiving replacement feeding, they should be given 4-6 weeks of infant prophylaxis with daily NVP (twice daily NRTI).

MONITORING THE RESPONSE TO ART AND DIAGNOSING TREATMENT FAILURE

Routine viral load monitoring can be carried out at 6 months, at 12 months, and then every 12 months thereafter if the patient is stable on ART to synchronize with routine monitoring and evaluation reporting for treatment.

Viral load is recommended as the preferred monitoring approach to diagnose and confirm treatment failure.

Viral failure is defined by a persistently detectable viral load exceeding 1000 copies/ml (that is, two consecutive viral load measurements within a 3-month interval, with adherence support between measurements) after at least 6 months of starting a new ART regimen.

Dried blood spot specimens using venous or capillary whole blood can be used to determine the HIV viral load. A threshold of 1000 copies/ml can be used to determine a virological failure when using dried blood spot samples, as defined for testing in plasma.

WHAT ART REGIMEN TO SWITCH TO (SECOND AND THIRD LINE)

Second-line ART for adults and adolescents

Second-line ART in adults should consist of two nucleoside reverse-transcriptase inhibitors (NRTIs) plus a ritonavir-boosted protease inhibitor (PI).

The following sequence of second-line NRTI options is recommended:

- After failure on a TDF + 3TC (or FTC)-based first-line regimen, use AZT + 3TC as the NRTI backbone in second-line regimens.
- After failure on an AZT or d4T + 3TC-based first-line regimen, use TDF + 3TC (or FTC) as the NRTI backbone in second-line regimens.

Use of NRTI backbones as a fixed-dose combination is recommended as the preferred approach.

Heat-stable fixed-dose combinations of ATV r and LPV/r are the preferred boosted PI options for second-line ART.
### Post-exposure prophylaxis (PEP) (24)

PEP for HIV consists of a comprehensive set of services to prevent infection developing in an exposed person, including: first aid care; counselling and risk assessment; HIV testing and counselling; and, depending on the risk assessment, the short term (28 days) provision of antiretroviral drugs, with support and follow-up.

**Eligibility for post-exposure prophylaxis**

1. Post-exposure prophylaxis should be offered, and initiated as early as possible, to all individuals with exposure that has the potential for HIV transmission, and ideally within 72 hours.

2. Assessment for eligibility should be based on the HIV status of the source whenever possible and may include consideration of background prevalence and local epidemiological patterns.

3. Exposures that may warrant post-exposure prophylaxis include:
   - a. parenteral or mucous membrane exposure (sexual exposure and splashes to the eye, nose or oral cavity); and
   - b. the following bodily fluids may pose a risk of HIV infection: blood, blood-stained saliva, breast-milk, genital secretions and cerebrospinal, amniotic, rectal, peritoneal, synovial, pericardial or pleural fluids.

<table>
<thead>
<tr>
<th>Second-line ART for children</th>
<th>National programme should develop policies for third-line ART</th>
</tr>
</thead>
<tbody>
<tr>
<td>After failure of a first-line regimen, children younger than 3 years should be switched to a RAL-based second-line regimen</td>
<td>Third-line regimens should include new drugs with minimal risk of cross-resistance to previously used regimes, such as INSTIs and second-generation NNRTIs and PIs</td>
</tr>
<tr>
<td>After failure of a first-line regimen containing AZT, d4T + 3TC (or FTC), the preferred NRTI backbone option for second-line ART is AZT + 3TC.</td>
<td>Patients on a failing second-line regimen with no new ARV options should continue with a tolerated regimen</td>
</tr>
<tr>
<td>After failure of a first-line regimen of ABC or TDF + 3TC (or FTC), the preferred NRTI backbone option for second-line ART is AZT + 3TC.</td>
<td></td>
</tr>
<tr>
<td>After failure of a first-line regimen containing AZT or d4T + 3TC (or FTC), the preferred NRTI backbone option for second-line ART is ABC or TDF + 3TC (or FTC).</td>
<td></td>
</tr>
</tbody>
</table>

**Preferred antiretroviral regimen for children < 10 years old**

AZT or d4T + 3TC (or FTC) is recommended as the regimen for PEP among children younger than 10 years, and second-generation NNRTIs and PIs are preferred as alternative options.

**Preferred antiretroviral regimens for adults and adolescents**

- TDF + 3TC for FTC, is recommended as the preferred backbone regimen for HIV post-exposure prophylaxis among adults and adolescents.
- LPV/r or ATV/r is recommended as the preferred third drug for HIV post-exposure prophylaxis among adults and adolescents.
- Where available, RAL, DRV/r or EFV can be considered as alternative options.

**Preferred antiretroviral regimen for children ≤ 10 years old**

AZT + 3TC is recommended as the preferred backbone regimen for HIV post-exposure prophylaxis among children 10 years and younger.

- ABC + 3TC or TDF + 3TC (or FTC) can be considered as alternative regimens.
- LPV/r is recommended as the preferred third drug for HIV post-exposure prophylaxis among children younger than 10 years.

An age-appropriate alternative regimen can be identified among ATV/r, RAL, DRV, EFV and NVP.

**Prescribing frequency**

A 28-day prescription of antiretroviral drugs should be provided for HIV post-exposure prophylaxis following initial risk assessment.

**Adherence support**

Enhanced adherence counseling is suggested for all individuals initiating HIV post-exposure prophylaxis.

All individuals potentially exposed to HIV should be encouraged to undergo HIV testing 3 months following exposure. Further testing after this time should be in accordance with WHO guidelines. Individuals diagnosed with HIV following PEP should be linked to treatment and care services as soon as possible. Risk reduction counseling should form part of each consultation with the individual. Use of condoms and safe injecting practices to prevent secondary transmission should be discussed. Blood donation should be avoided while the individual is taking PEP following a possible HIV exposure and while still in the window period for HIV acquisition and testing (24).
Use of co-trimoxazole prophylaxis for HIV-related infections (24)

Co-trimoxazole is a fixed dose combination of two antimicrobial drugs (sulfamethoxazole and trimethoprim) that covers a variety of bacterial, fungal, and protozoan infections. The therapy is feasible, well tolerated, and inexpensive intervention for people living with HIV to reduce HIV-related morbidity and mortality. The WHO recommendations (2016) for the use of co-trimoxazole is summarized in Table 5.

</tr>
</tbody>
</table>

| An age-appropriate alternative regimen can be identified among ATV/ RAL/ DRV/ ETV and NVP. |

HIV and Tuberculosis

Despite being preventable and curable, TB is the leading cause of HIV-associated mortality. Xpert MTB/RIF should be used rather than conventional microscopy, culture, and drug susceptibility testing (DST) as the initial diagnostic test in adults and children suspected of having HIV-associated TB or multidrug-resistant TB. Isoniazid preventive therapy and ART, given together, can reduce the risk of TB among people living with HIV by up to 97 per cent. For details, refer to page 218.

Monitoring the efficacy of ART

Efficacy is monitored by (21)

- (a) clinical improvement
  - gain in body weight,
  - decrease in occurrence and severity of HIV-related diseases (infections and malignancies),
- (b) increase in total lymphocyte count,
- (c) improvement in biological markers of HIV (when available)
  - CD4 + T-lymphocyte counts,
  - plasma HIV RNA levels.

3. Specific prophylaxis

Until more effective antiviral therapy becomes available, the main aim of existing therapies will be to treat the manifestations of AIDS. Primary prophylaxis against P. carinii pneumonia should be offered to patients with CD4 count below 200 cells/µL. The regimen available is trimethoprim-sulfamethoxazole, aerosolized pentamidine, and dapsone. Patients who develop P. carinii infection on a particular prophylactic regimen should be switched to the other drug or should receive a combination regimen.

M. avium complex occurs in at least one third of AIDS patients. Rifabutin has been shown in a randomized trial to decrease the incidence of disseminated M. avium-intracellulare in persons with less than 200 CD4 cells/µL. Clinicians should consider that patients do not have active M. tuberculosis infection before starting Rifabutin. Prophylaxis against M. tuberculosis is 300 mg isoniazid daily for 9 months to one year. It should be given to all HIV-infected patients with positive PPD reactions (defined for HIV-infected patients as more than 5 mm in induration). Kaposis's sarcoma might be treated in some stage with interferon, chemotherapy or radiation. Cytomegalovirus retinitis can be controlled by ganciclovir, cryptococcal meningitis with fluconazole. Esophageal candidiasis or recurrent vaginal candidiasis can be treated by fluconazole or ketoconazole. Herpes simplex infection and herpes zoster can be treated with acyclovir or foscarnet.

4. Primary health care

Because of its wide-ranging health implications, AIDS touches all aspects of primary health care, including mother and child health, family planning, and education. It is important, therefore, that AIDS control programmes are not developed in isolation. Integration into country's primary health care system is essential.

National AIDS Control Programme

Refer to chapter 7, page 465 for details.

Emerging and re-emerging infectious diseases

Today the world stands on the threshold of a new era in which hundreds of millions of people will be safe from some of the most terrible diseases. Soon poliomyelitis, neonatal tetanus, guineaworm disease, river blindness, Chagas’ disease will join smallpox as diseases of the past. On the other hand, the world also stands on the brink of a global crisis in infectious diseases. No country is safe from them and no country can afford to ignore their threat any longer. The optimism of a relatively few years ago that many of the most terrible diseases will be conquered, have returned with a vengeance. Others have previously unknown diseases continue to emerge (Table 1).

The factors responsible for emergence and re-emergence of infectious diseases are: (1) unplanned and unplanned urbanization; (2) overcrowding and rapid population growth; (3) poor sanitation; (4) inadequate public health infrastructure; (5) resistance to antibiotics; (6) increased exposure of humans to disease vectors and reservoirs of infection in nature; (7) rapid and intense international travel; and (8) microbial genetic mutation.

Emerging diseases

During the past 30 years, at least 30 new diseases have emerged to threaten the health of hundreds of millions of people. For many of these diseases there is no treatment, cure or vaccine and the possibility of preventing or controlling them is limited. Emerging infectious diseases are those whose incidence in humans has increased during the last two decades or which threaten to increase in the near future. The term also refers to newly-appearing infectious diseases, or diseases that are spreading to new geographical areas – such as cholera in South America and yellow fever in Kenya.

The diseases in question involve all the major modes of transmission – they are spread either from person to person, by insects or animals, or through contaminated water or food. The most dramatic example of a new disease is AIDS, caused by the human immunodeficiency virus (HIV). The existence of the virus was unknown until 1983. Presently, estimated 2.3 million cases occur every year worldwide. For more details, please refer to page 371.

A new breed of deadly haemorrhagic fevers, of which Ebola virus disease (previously known as Ebola haemorrhagic fever) is the most notorious, has struck in Africa. Ebola appeared for the first time in Zaire and Sudan in 1976. Since then it has appeared periodically. Ebola virus is a member of Filoviridae family and comprises of 5 distinct species – Zaire ebolavirus; Reston ebolavirus; Sudan ebolavirus; Tai ebolavirus; and Bundibugyo ebolavirus. The recent epidemic started in December 2013 in Guinea and spread to South Africa. By 8th April 2015, a total of 25,515 cases have been reported with over 10,000 deaths. Case fatality rate may be as high as 70 per cent. Ebola has incubation period of 2–21 days, and is not infectious during this period. Asymptomatic cases are also not infectious. The virus is transmitted through direct contact with the blood, organs, body secretions or other body fluids of infected animals like chimpanzees, gorillas, monkeys, fruit bats etc. Human to human transmission is through blood or body fluids of an infected symptomatic person or through exposure to objects (such as needles) that have been contaminated with infected secretions. It is not transmitted through air, water or food. The illness is characterized by sudden onset of fever, intense weakness, muscle pain, headache, sore throat, vomiting, diarrhea, rash, impaired kidney and liver functions and in some cases both internal and external bleeding. Currently there is no specific treatment for this disease. However, by intensive supportive care, the mortality can be reduced and spread of the disease can be prevented by instituting specific infection control measures. There is no vaccine against ebola (1).

The United States has seen the emergence of hantavirus pulmonary syndrome, characterized by respiratory failure and a case fatality rate of over 50%. Since it was first recognized in 1993, this type of hantavirus infection has been detected in more than 20 states in that country, and has also surfaced in Argentina and Brazil. This hantavirus is carried by rodents, particularly deer mice. Other hantaviruses have been recognized for many years in Asia, where they cause haemorrhagic fever with renal involvement in humans.

Epidemics of foodborne and waterborne diseases due to new organisms such as cryptosporidium or new strains of bacteria such as Escherichia coli have hit industrialized and developing countries alike. The O157:H7 strain of E. coli was first reported in 1982 and has since then been
Implicated in many serious outbreaks of diarrhoeal illness, sometimes leading to kidney failure. The strain has been linked to undercooked hamburger beef and unpasteurized milk. A completely new strain of cholera, 0139, appeared in South-eastern India in 1992 and has since spread north and west to other areas of India, into western China, Thailand and other parts of South-East Asia.

The threat of a new global influenza pandemic is increasing. Major shifts in the make-up of influenza viruses occur every 20 years or so, triggering large epidemics in many parts of the world, and causing many thousands of deaths. The next such shift is expected to take place very soon. Epidemic strains of influenza viruses originate from China. The influenza virus is carried by ducks, chickens and pigs raised in close proximity to one another on farms. The exchange of genetic material between these viruses produces new strains, leading to epidemics of human influenza, each epidemic being due to a different strain. Currently avian H5N1 is the strain with pandemic potential, since it might adapt into a strain that is contagious among humans. Since 1997, 478 cases with 286 deaths have been reported to WHO. The first case was from Hong Kong. Other countries involved are Cambodia, Indonesia, Thailand and Viet Nam (4). In late 2002, a new disease called SARS was reported from China with rapid spread to Hong Kong, Singapore, Viet Nam, Taiwan, and Toronto. During 2003, 8,422 SARS cases were reported from 30 countries with 916 fatalities (5). More recently, pandemic due to influenza A (H1N1) 2009 strain is continuing worldwide involving 214 countries, already taking 18,156 lives. New strains such as those of cholera and influenza do not follow the usual pattern of being more common in younger people. They affect all age groups, since older people have not acquired immunity to them from previous infection.

Table 1 summarizes the aetiological agents and infectious diseases in humans and/or animals recognized since 1973. The year may differ from first appearance and first identification of cases.

Re-emerging diseases

The term re-emerging diseases refers to the diseases which were previously easily controlled by chemotherapy and antibiotics, but now they have developed antimicrobial resistance and are often appearing in epidemic form.

The emergence of drug-resistant strains of microorganisms or parasites is promoted by treatments that do not result in cure. The increasing use of antimicrobials worldwide, often in subtherapeutic doses and sometimes in counterfeit form, indicates that this problem will increase in the foreseeable future. Changes in lifestyle, behaviour (including injecting and non-injecting drug use) and cultural or social values are behind the emergence of some infectious diseases such as syphilis. Increases in the number of sexual partners have been the main factor in the spread of HIV infection and other sexually transmitted diseases. Travel, including tourism, also plays a role. The spread of syphilis in the 18th and 19th centuries was related to the movement of armies. Today, the introduction of HIV in many parts of the world is due to greatly increased human mobility. Studies show that whereas only a few generations ago most people in their lifetime travelled no further than 40 kilometres from their birthplace, many today go up to 1,000 times further, travelling the whole world.

The practices of modern medicine also contribute. The spread of viral hepatitis is related in part to techniques such as kidney dialysis and multiple blood transfusions, as well as to other forms of transmission. Relaxation in immunization practices can quickly result in the resurgence of diseases, as for example, the recent spread of diphtheria in the Russian Federation and other former republics of the USSR.

New animal diseases pose potential foodborne risks to human health that are sometimes difficult to evaluate or predict. An example that has caused much public concern in Europe is bovine spongiform encephalopathy ("mad cow disease"). Fears have grown that the infectious agent responsible may be passed through the food chain to cause a variant of the incurable Creutzfeldt–Jakob disease in humans, in which the brain is attacked. The British beef market has been seriously affected and stringent public health safeguards have been introduced.

The reasons for outbreaks of new diseases, or sharp increases in those once believed to be under control, are complex and still not fully understood. The fact is however, that national health has become an international challenge. An outbreak anywhere must now be seen as a threat to virtually all countries, especially those that serve as major hubs of international travel. Despite the emergence of new diseases in the last 30 years, there is still a lack of national and international political will and resources to develop and support the systems that are necessary to detect them and stop their spread. Without doubt diseases as yet unknown, but with the potential to be the AIDS of tomorrow, lurk in the shadows.

Antimicrobial resistance

Resistance by disease-causing organisms to antimicrobial drugs and other agents is a major public health problem worldwide. It is making a growing number of infections virtually untreatable, both in hospitals and in the general community. It is having a deadly impact on the control of diseases such as tuberculosis, malaria, cholera, dysentery and pneumonia.

Antimicrobial resistance is not a new problem, but it has worsened dramatically in the last decade. During that time, the pace of development of new antimicrobials has slowed down while the prevalence of resistance has grown at an alarming rate. The increase in the number of drug-resistant bacteria is no longer matched by a parallel expansion in the arsenal of agents used to treat infections. There is strong evidence that a major cause of the current crisis in antimicrobial resistance is the uncontrolled and inappropriate use of antibiotic drugs, in both industrialized and developing countries. They are used by too many people to treat the wrong kind of infection, in the wrong dosage and for the wrong period of time. The implications are awesome: drugs that cost tens of millions of dollars to produce, and take perhaps 10 years to reach the market, have only a limited life span in which they are effective. As resistance spreads, the life span shrinks; as fewer new drugs appear, the gulf widens between infection and control. So far, the pattern of excessive or inappropriate use and the development of resistance has been repeated after the introduction of each new antimicrobial. The over-use of expensive drugs designed to cover a range of infections is a particularly serious problem in industrialized countries. In developing countries, the problem is compounded by the ready availability of over-the-counter drugs. This allows patients to treat themselves, either with the wrong medicine, or in quantities that are too small to be effective. Substandard and counterfeit drugs which lack adequate amounts of active ingredients further exacerbate the resistance problem.

The examples of bacterial resistance are as follows:

Strains of *M. tuberculosis* resistant to anti-tuberculosis drugs are widespread, although attention has recently focused on the alarming outbreaks of tuberculosis caused by multidrug-resistant strains in the United States. Drug resistance is the result of poor prescribing practices, or poor patient compliance with treatment. It is low in the few countries with effective tuberculosis programmes. The most dangerous form of the multidrug-resistant disease occurs when cases become virtually incurable and doctors face situations similar to those of the pre-antibiotic era.

Malaria presents a double resistance problem: resistance of the *Plasmodium* parasites, which cause the disease, to antimalarial drugs; and resistance of the *Anopheles* mosquitoes, the vectors of the disease, to insecticides. The arsenal of antimalarial drugs is limited. Most of them act by killing parasites when they are multiplying in the blood stream of the human host. Unfortunately, due to inadequate regimens, poor drug supply, and poor quality and misuse of drugs, rapid development of drug resistance has occurred in most areas of the world. Drug resistance is particularly important in falciparum malaria, the most severe form of the disease. Resistance to chloroquine, the most commonly used drug, has been found in all endemic countries except those of Central America and the Caribbean. Resistance to multiple drugs is common in South-East Asia. This serious obstacle to malaria control efforts is further complicated by mosquito resistance to insecticides. Many mosquitoes are reported to be resistant to the three classes of insecticides available for public health use, and some are becoming resistant to pyrethroids, widely promoted for bed-net and curtain impregnation.

Enterococci contribute to some of the most common infections acquired in hospitals, causing intra-abdominal abscesses, endocarditis, and infections of the urinary tract.
and soft tissues. In some countries, infections resulting from strains resistant to the main groups of antibiotics, such as the beta-lactams and the aminoglycosides, can only be treated with vancomycin, an expensive intravenous drug. Even resistance to vancomycin has developed in the last 10 years or so. Staphylococci, which can contribute to skin infections, endocarditis, osteomyelitis, food poisoning and other serious disorders, have developed resistance to all antibiotics except vancomycin. If vancomycin-resistant strains were to emerge, some of the most prevalent hospital-acquired infections would become virtually untreatable.

Streptococci have become increasingly resistant to some antibiotics. They are among the most common disease-causing bacteria, responsible for infections of the throat, middle ear, skin and wounds, and also necrotizing fasciitis and gangrene. Pneumococci and *Haemophilus influenzae* are the most common bacteria causing acute respiratory infections in children, particularly pneumonia. Both of these organisms are becoming more and more resistant to drugs. Strains of pneumococci, once uniformly susceptible to penicillin, are currently resistant to it in up to 18% of cases in the United States and 40% in South Africa. In addition, they are becoming resistant to many other commonly used antibiotics, including cotrimoxazole, the drug recommended by WHO for treatment of pneumonia. The most virulent type of *Haemophilus influenzae* is today frequently resistant to ampicillin, and strains have been identified that are resistant to other drugs, including cotrimoxazole. In brief, doctors worldwide are losing some of the most useful and affordable antibiotics against the two bacteria which are the major cause of death in children.

*Neisseria gonorrhoeae*, cause of one of the most common sexually transmitted diseases, has acquired such resistance to penicillin and tetracyclines in most countries that the use of these antibiotics to treat it has become unacceptable and this infection now requires the use of much more expensive drugs which are often unavailable.

*Shigella dysenteriae* has been causing outbreaks of severe diarrhoeal disease in central and southern Africa in recent years, including those in refugee camps, with the epidemic strain acquiring increasing resistance to standard antibiotics. Epidemic dysentery caused by this strain results in the death of up to 15% of those infected. *Salmonella typhi*, the bacterium responsible for typhoid fever, has developed resistance to antibiotics commonly used in the past for treatment. Resistant strains have caused outbreaks of the disease in India and Pakistan. Without effective antibiotic treatment, typhoid fever kills almost 10% of those infected. In South-East Asia, 50% or more of the strains of the bacteria may already be resistant to several antibiotics.

More than half of the antibiotics produced worldwide are used in animals, largely in subtherapeutic concentrations which favour the onset of drug resistance. As a result, two important human pathogens of animal origin, *E.coli* and salmonellae, are today highly resistant to antibiotics in both industrialized and developing countries. For instance, in the United Kingdom, the increase of multidrug-resistant strains of *Salmonella typhimurium* isolated from cattle is paralleled by increasing resistance among strains of human origin. In Thailand, salmonellae isolated from food animals are also highly resistant to the common antibiotics. These bacteria cause diarrhoeal disease and can lead to life-threatening complications. Due to the globalization of food supply and international travel, antimicrobial resistance among animal bacteria can affect consumers anywhere in the world.

Together, these factors have created perhaps the richest opportunities ever for the spread of infections, many of which become global problems that make the first line of defence — early recognition and adequate and timely response — essential.

**Responding to epidemics**

The process of response encompasses a multitude of activities including: diagnosis of the disease; investigation to understand the source of transmission; implementation of control strategies and programmes; research to develop adequate means to treat the disease and prevent its spread; and the production and distribution of the necessary drugs and vaccines.

The strategy for controlling re-emerging diseases is through available cost-effective interventions such as early diagnosis and prompt treatment, vector control measures and the prevention of epidemics, for malaria; and DOTS—directly observed treatment, short-course — for tuberculosis: by launching research initiatives for treatment regimens and improved diagnostics, drugs and vaccines; and above all by strengthening epidemiological surveillance and drug-resistance surveillance mechanisms and procedures with appropriate laboratory support for early detection, confirmation and communication.

The category of diseases — "new diseases — new problems" — such as Ebola and other viral haemorrhagic fevers, is probably the most frightening. The need, therefore, is for expanding research on infectious disease agents, their evolution, the vectors of disease spread and methods of controlling them, and vaccines and drug development. Much of this already applies to HIV/AIDS, one of the most serious diseases to emerge in recent decades.

**References**

1. WHO (2014), Fact Sheet on Ebola Viral Disease, No. 103, Sept. 2014

**Hospital-acquired infection**

Hospital-acquired infection is cross infection of one patient by another or by doctors, nurses and other hospital staff, while in hospital. A high frequency of nosocomial infection is evidence of a poor quality of health service delivery. Many factors contribute to the frequency of nosocomial infections: hospitalized patients are often immunocompromised, they undergo invasive examinations and treatments, and patient care practices and the hospital environment may facilitate the transmission of microorganisms among patients. The selective pressure of intense antibiotic use promotes antibiotic resistance. While progress in the prevention of nosocomial infections has been made, changes in medical practice continually present new opportunities for development of infection.

**Definition of nosocomial infections**

Nosocomial infections, also called "hospital-acquired infections", are infections acquired during hospital care which are not present or incubating at admission. Infections occurring more than 48 hours after admission are usually considered nosocomial. Definitions to identify nosocomial
infections have been developed for specific infection sites (e.g. urinary, pulmonary).

Nosocomial infections may also be considered either endemic or epidemic. Epidemic infections are most common. Nosocomial infections may also be considered either endemic or epidemic. Epidemic infections occur during outbreaks, defined as an unusual increase above the baseline of a specific infection or infecting organism.

Changes in health care delivery have resulted in shorter hospital stays and increased outpatient care. It has been suggested that the term nosocomial infections should encompass infections occurring in patients receiving treatment in any health care setting. Infections acquired by staff or visitors to the hospital or other health care setting may also be considered nosocomial infections.

Simplified definitions may be helpful for some facilities without access to full diagnostic techniques. Table 1 provides definitions for common infections that could be used for surveys in facilities with limited access to sophisticated diagnostic techniques.

According to a French National Prevalence Survey the distribution of sites of nosocomial infection are as shown in Fig. 1.

Hospital-acquired infection may be considered from three angles:

1. Source
2. Routes of spread; and
3. Recipients.

### 1. Sources

The sources are patients, hospital staff and the environment. (a) PATIENTS: Patients suffering from infectious diseases are potential sources of infection. These cases may be certain viral infections (measles, German measles, influenza, viral hepatitis); Skin infections (discharging wounds, infected skin lesions, eczema, psoriasis, boils, bed sores); respiratory infections (acute throat, pneumonia, tuberculosis, chest infection); and urinary tract infection (B. coli infection). All these are very common sources of hospital acquired infection.

(b) STAFF: The hospital staff (viz. doctors, nurses, ward boys) who come in close contact with patients may often be an important source of cross infection. For example, staphylococcus aureus is commonly carried in the nose or on the skin. Haemolytic streptococci may be carried in the throat and salmonella in the gut. (c) ENVIRONMENT: The hospital environment (viz. hospital dust, linen, bed clothes, furniture, sinks, basins, door handles and even the air) is laden with microorganisms, and is thus an important source of infection.

### 2. Routes of spread

The common routes of spread of cross infection are:

(a) Direct contact, i.e. the organism may be transferred directly from the hands of a nurse or doctor to a susceptible patient; (b) Droplet infection, e.g. droplets released from nose and throat through coughing or sneezing; (c) Air-borne particles; (d) Release of hospital dust into the air; (e) Through various hospital procedures, viz., catheterization, intravenous procedures, infected cat gut, dressings, sputum cups, bed pans, urinals etc.

### 3. Recipients

All patients in hospitals are potential recipients of cross infection. Some patients are more susceptible than others, especially those who are severely ill and those under corticosteroid therapy. Cross infection is greater in intensive care units, urological and geriatric wards and in special baby care units.

### Preventive measures

The main preventive measures are:

(a) Isolation: Infectious patients must be isolated. Patients who are susceptible to infection should not be placed in beds next to patients who are a source of infection.

(b) Hospital staff: Those who are suffering from skin diseases, sore throat, common cold, ear infection, diarrhoea or dysentery and other infectious ailments should be kept away from work until completely cured. They should be careful about personal hygiene and in regular changes of aprons and outer clothing.

(c) Hand washing: The most common route of infection is via the hands. When dealing with patients, hand washing must be thorough. When hand washing with soap and water is not sufficient, a suitable alcohol-based disinfectant must be employed for hand-washing. In the year...
2009, WHO developed guidelines for hand hygiene known as “Clean Care is Safer Care”. It should be followed to improve the standards of hand hygiene practices (2).

(d) Dust control: Hospital dust contains numerous bacteria and viruses. The dust is released during sweeping, dusting and bed making. Suppression of dust by wet dusting and vacuum cleaning are important control measures.

(e) Disinfection: The articles used by the patient as well as patient's urine, faeces, sputum should be properly disinfected. Proper sterilization of instruments should be enforced.

(f) Control of droplet infection: Use of face masks, proper bed spacing, prevention of overcrowding and ensuring adequate lighting and ventilation are important control measures.

(g) Nursing techniques: Barrier nursing and task nursing have also been recommended to minimize cross infection.

(h) Administrative measures: There should be a hospital “Control of Infection Committee” to formulate policies regarding admission of infectious cases, isolation facilities, disinfection procedures, and in fact all matters relating to control of hospital acquired infection.

The four most common nosocomial infections are urinary tract infections, surgical wound infections, pneumonia, and primary bloodstream infection. Each of these is associated with an invasive medical device or invasive procedure. Specific policies and practices to minimize these infections must be established, reviewed and updated regularly, and compliance monitored, as shown in Table 2.

### Standard (routine) precautions

Standard precautions should be applied to the care of all patients. This includes limiting health care worker contact with all secretions or biological fluids; skin lesions, mucous membranes, and blood or body fluids. Health care workers must wear gloves for each contact which may lead to contamination, and also gown, mask and eye protection where contamination of clothes or the face is anticipated.

Considerations for protective clothing include:
- gown: should be of washable material, buttoned or tied at the back and protected, if necessary, by a plastic apron
- gloves: inexpensive plastic gloves are available and usually sufficient
- mask: surgical masks made of cloth or paper may be used to protect from splashes.

Standard precautions for all patients are as follows:
- Wash hands promptly after contact with infective material
- Use no touch technique wherever possible.
- Wear gloves when in contact with blood, body fluids, secretions, excretions, mucous membranes and contaminated items.
- Wash hands immediately after removing gloves.
- All sharps should be handled with extreme care.

Note: The table provides a summary of measures for preventing infection in various settings, highlighting both effective and ineffective strategies. Further details are provided to support evidence-based practices in healthcare settings.
- Clean up spills of infective material promptly.
- Ensure that patient-care equipment, supplies and linen contaminated with infective material is either discarded, or disinfected or sterilized between each patient use.
- Ensure appropriate waste handling.
- If no washing machine is available for linen soiled with infective material, the linen can be boiled.

Health care workers are at risk of acquiring infection through occupational exposure. Hospital employees can also transmit infections to patients and other employees. Thus, a programme must be in place to prevent and manage infections in hospital staff.

Employee’s health should be reviewed at recruitment, including immunization history and previous exposure to communicable diseases (e.g. tuberculosis) and immune status. Some previous infections (e.g. varicella-zoster virus (VZV)) may be assessed by serological tests.

Immunizations recommended for staff include: hepatitis A and B, yearly influenza, measles, mumps, rubella, tetanus, and diphtheria. Immunization against varicella may be considered in specific cases. The Mantoux skin test will document a previous tuberculosis infection and must be obtained as a base-line.

Specific postexposure policies must be developed, and compliance ensured for: human immunodeficiency virus (HIV), hepatitis A virus, hepatitis B virus, hepatitis C virus, Neisseria meningitidis, Mycobacterium tuberculosis, varicella-zoster virus, hepatitis E virus, Corynebacterium diphtheriae, Bordetella pertussis, and rabies.

Reference
Chronic diseases and conditions have been variously defined. An EURO symposium in 1957 (1) gave the following definition:

"An impairment of bodily structure and/or function that necessitates a modification of the patient’s normal life, and has persisted over an extended period of time."

Another EURO symposium in 1965 (2) observed:

"Upto now no widely acceptable definition (of acute or chronic patients) has been found. Some authors maintain that an acute illness usually consists of a simple episode of fairly short duration from which the patient returns to normal activity, whereas a chronic illness is one of long duration in which the patient is permanently incapacitated to a more or less marked degree. There is also the view that progress in the technology of resuscitation and haemobiology has blurred the borderline between acute and chronic conditions."

The Commission on Chronic Illness in USA (3) has defined “chronic diseases” as “comprising all impairments or deviations from normal, which have one or more of the following characteristics:

- are permanent
- leave residual disability
- are caused by non-reversible pathological alteration
- require special training of the patient for rehabilitation
- may be expected to require a long period of supervision, observation or care.”

In short, there is no international definition of what duration should be considered long-term (4), although many consider that chronic conditions are generally those that have had a duration of at least 3 months (5). A practical definition should be established which will suit the particular conditions of the community (4).

Non-communicable diseases (NCDs) include cardiovascular, renal, nervous and mental diseases, musculoskeletal conditions such as arthritis and allied diseases, chronic non-specific respiratory diseases (e.g., chronic bronchitis, emphysema, asthma), permanent results of accidents, senility, blindness, cancer, diabetes, obesity and various other metabolic and degenerative diseases and chronic results of communicable diseases. Disorders of unknown cause and progressive course are often labelled “degenerative”.

The problem

Chronic non-communicable diseases are assuming increasing importance among the adult population in both developed and developing countries. Cardiovascular diseases and cancer are at present the leading causes of death in developed countries. The prevalence of chronic disease is showing an upward trend in most countries, and for several reasons this trend is likely to increase. For one reason, life expectancy is increasing in most countries and a greater number of people are living to older ages, and are at greater risk to chronic diseases of various kinds. For another, the life-styles and behavioural patterns of people are changing rapidly, these being favourable to the onset of chronic diseases. Modern medical care is now enabling many with chronic diseases to survive. The impact of chronic diseases on the lives of people is serious when measured in terms of loss of life, disablement, family hardship and poverty, and economic loss to the country. Developing countries are now warned to take appropriate steps to avoid the “epidemics” of non-communicable diseases likely to come with socio-economic and health developments.

A total of 57 million deaths occurred worldwide during 2016. Of these, 41 million were due to NCDs, principally cardiovascular diseases, cancer and chronic respiratory diseases. Nearly three quarters of these NCD deaths (28 million) occurred in low- and middle-income countries. The number of NCD deaths has increased worldwide and in every region since year 2000, when there were 31 million NCD deaths. The leading cause of NCD death in 2016 were: cardiovascular diseases (17.9 million deaths or 44 per cent of NCD deaths), cancers (9 million or 16 per cent of NCD deaths), respiratory disease, including asthma and chronic obstructive pulmonary disease (3.8 million or 9 per cent of NCD deaths), and diabetes (1.6 million or 4 per cent of NCD deaths) (6). In 2016, the age standardized NCD death rate was 539 per 100,000 population globally. The rate was lowest in high-income countries (397 per 100,000) and highest in low-income countries (625 per 100,000) and lower-middle income countries (673 per 100,000). Approximately 42 per cent of the deaths were before the age of 70 years (7).

India is experiencing a rapid health transition with a rising burden of NCDs causing significant morbidity and mortality, both in urban and rural population, with
considerable loss in potentially productive years (age 35–64 years) of life. NCDs are estimated to account for about 63 per cent of all deaths. India shares more than two-thirds of the total deaths due to NCDs in the SEAR of WHO. Four types of NCDs—cardiovascular diseases, cancer, chronic respiratory diseases and diabetes—make the largest contribution to morbidity and mortality due to NCDs. Four behavioural risk factors are responsible for significant proportions of these diseases—tobacco use, unhealthy diet, physical inactivity and harmful use of alcohol. Major metabolic risk factors are obesity, raised blood pressure, raised blood glucose and raised total cholesterol levels. The probability of dying between ages 30 and 70 years from four major NCDs is 23 per cent (27 per cent in men and 20 per cent in women), which means that a 30-year-old individual has a one-fourth chance of dying from these diseases before the age of 70 years. Fig. 1 shows the proportional mortality in the country.

**Non-communicable disease risk factors**

Most epidemiologists accept that a set of "risk factors" are responsible for a major share of adult non-communicable disease morbidity and premature mortality. A large percentage of NCDs are preventable through the changes in these factors. The influences of these risk factors and other underlying metabolic/physiological causes, on the non-communicable disease epidemic include (7):

- **Tobacco**: Almost 7 million people die from tobacco use each year, both from direct tobacco use and second-hand smoke. About 600,000 deaths are caused by second-hand smoke, of these 170,000 are children. In 2016, there were 1.1 billion smokers worldwide with over 80% every day smokers (10). By 2020, this number will increase to 7.5 million, accounting for 10% of all deaths. Smoking is estimated to cause about 71% of lung cancer, 42% of chronic respiratory disease and nearly 10% of cardiovascular disease. The highest incidence of smoking among men is in lower-middle-income countries; for total population, smoking prevalence is highest among upper-middle-income countries.

- **Insufficient physical activity**: Approximately 1.6 million people die each year due to physical inactivity (11). People who are insufficiently physically active have a 20% to 30% increased risk of all-cause mortality. Regular physical activity reduces the risk of cardiovascular disease, including high blood pressure, diabetes, breast and colon cancer and depression. Insufficient physical activity is highest in high-income countries, but very high levels are now also seen in some middle-income countries especially among women.

- **Harmful use of alcohol**: Approximately 3.3 million people die each year from the harmful use of alcohol, accounting for about 5.9% of all deaths in the world and 5.1 per cent DALYs were attributable to alcoholism (10). More than half of these deaths occur from NCDs including cancers, cardiovascular disease and liver cirrhosis. Moreover there is a close relationship between drinking and violent crime including domestic violence. Alcohol related harm is determined by three related dimensions: the volume of alcohol consumed, the pattern of drinking and quality of alcohol consumed (10). While adult per capita consumption is highest in high-income countries, it is nearly as high in the populous upper-middle-income countries.

- **Unhealthy diet**: Adequate consumption of fruit and vegetables reduces the risk for cardiovascular diseases, stomach cancer and colorectal cancer. Most populations consume much higher levels of salt than recommended by WHO for disease prevention; high salt consumption is an important determinant of high blood pressure and cardiovascular risk. 4.1 million deaths from CVD causes have been attributed to excess salt/sodium intake (11). High consumption of saturated fats and trans-fatty acids is linked to heart disease. Unhealthy diet is rising quickly in lower-resource settings. Available data suggest that fat intake has been rising rapidly in lower-middle-income countries since the 1980s.
Raised blood pressure: Raised blood pressure is estimated to cause 9.4 million deaths, about 12.8% of all deaths. It is a major risk factor for cardiovascular disease. The prevalence of raised blood pressure is similar across all income groups. During the year 2015, the global prevalence of raised blood pressure in adults 18 year and above was around 22 per cent (10).

Overweight and obesity: At least 2.8 million people die each year as a result of being overweight or obese. Risks of heart disease, stroke and diabetes increase steadily with increasing body mass index (BMI). Raised BMI also increases the risk of certain cancers. The prevalence of overweight is highest in upper-middle-income countries, but very high levels are also reported from some lower-middle-income countries. In the year 2016, 11% of men and 15% of women aged 18 years and above were obese. More than 42 million children under the age of 5 years were overweight in 2015 (10). Factors driving this rise include poor diet and lack of exercise. Many children are growing up in a society which promotes high energy intake while encouraging physical inactivity. Most of these children will become obese adults, which makes them more susceptible to develop NCDs (10).

Raised cholesterol: Raised cholesterol is estimated to cause 2.6 million deaths annually; it increases the risk of heart disease and stroke. Raised cholesterol is highest in high-income countries.

Cancer-associated infections: At least 2 million cancer cases per year, 18% of the global cancer burden, are attributable to a few specific chronic infections, and this fraction is substantially larger in low-income countries. The principal infectious agents are human papillomavirus, Hepatitis B virus, Hepatitis C virus and Helicobacter pylori. These infections are largely preventable through vaccinations and measures to avoid transmission, or treatable. For example, transmission of Hepatitis C virus has been largely stopped among high-income populations, but not in many low-resource countries.

Environmental risk factors: occupational hazards, air and water pollution, and possession of destructive weapons in case of injuries.

Gaps in natural history

There are many gaps in our knowledge about the natural history of chronic diseases. These gaps cause difficulties in aetiological investigations and research (12). These are:

1. Absence of a known agent

   There is much to learn about the cause of chronic diseases. Whereas in some chronic diseases the cause is known (e.g., silica in silicosis, asbestos in mesothelioma), for many chronic diseases the causative agent is not known. The absence of a known agent makes both diagnosis and specific prevention difficult.

2. Multifactorial causation

   Most chronic diseases are the result of multiple causes — rarely is there a simple one-to-one cause-effect relationship. In the absence of a known agent, the term “risk factor(s)” is used to describe certain factors in a person’s background or life-style that make, the likelihood of the chronic condition more probable. Further, chronic diseases appear to result from the cumulative effects of multiple risk factors. These factors may be both environmental and behavioural, or constitutional. Epidemiology has contributed massively in the identification of risk factors of chronic diseases. Many more are yet to be identified and evaluated.

3. Long latent period

   A further obstacle to our understanding of the natural history of chronic disease is the long latent (or incubation) period between the first exposure to “suspected cause” and the eventual development of disease (e.g., cervical cancer). This makes it difficult to link suspected causes (antecedent events) with outcomes, e.g., the possible relation between oral contraceptives and the occurrence of cervical cancer. In an attempt to overcome this problem, a search has been made for precursor lesions in, for example, cancer cervix, oral cancer and gastric cancer. But this is not possible in all chronic diseases. However, it has now become increasingly evident that the factors favouring the development of chronic disease are often present early in life, preceding the appearance of chronic disease by many years. Examples include hypertension, diabetes, stroke, etc.

4. Indefinite onset

   Most chronic diseases are slow in onset and development, and the distinction between diseases and non-diseased states may be difficult to establish (e.g., diabetes and hypertension). In many chronic diseases (e.g., cancer) the underlying pathological processes are well established long before the disease manifests itself. By the time the patient seeks medical advice, the damage already caused may be irreversible or difficult to treat.

Prevention

The preventive attack on chronic diseases is based on the knowledge that they are multifactorial in causation, so their prevention demands a complex mix of interventions. Previously only tertiary prevention seemed possible to prevent or delay the development of further disability or the occurrence of premature death. But, now, with the identification of risk factors, health promotion activities aimed at primary prevention are being increasingly applied in the control of chronic diseases. Some of the interventions that should be undertaken immediately to produce accelerated results in terms of lives saved, disease prevented and heavy cost avoided are as follows (13):

1. Protecting people from tobacco smoke and banning smoking in public places, warning about the dangers of tobacco use, enforcing bans on tobacco advertising, promotion and sponsorships and raising taxes on tobacco;
2. Restricting access to retailed alcohol, enforcing bans on alcohol advertising and raising taxes on alcohol;
3. Reduce salt intake and salt content of food;
4. Replacing trans-fat in food with polyunsaturated fat; and
5. Promoting public awareness about diet and physical activity, including through mass media.

In addition, there are many other cost-effective and low-cost population-wide interventions that can reduce risk factors for NCDs. These include:

1. Nicotine dependence treatment;
2. Enforcing drink-driving laws;
3. Restrictions on marketing of foods and beverages high in salt, fats and sugar;
4. Food taxes and subsidies to promote healthy diets;
5. Healthy nutrition environments in schools.
6. Nutrition information and counselling in health care;

There also are population-wide interventions that focus on cancer prevention, like vaccination against Hepatitis B, a major cause of liver cancer. Vaccination against human papillomavirus (HPV), the main cause of cervical cancer, is also recommended. Protection against environmental or occupational risk factors for cancer, such as aflatoxin, asbestos and contaminants in drinking-water can be included in effective prevention strategies.

Present knowledge indicates that the chronically ill require a wide spectrum of services — case finding through screening and health examination techniques; application of improved methods of diagnosis, treatment and rehabilitation; control of food, water and air pollution; reducing accidents; influencing patterns of human behaviour and life-styles through intensive education; upgrading standards of institutional care and developing and applying better methods of comprehensive medical care including primary health care. Political approaches are also needed as in the case of smoking control, control of alcohol and drug abuse. The approach should be holistic in handling the complex medical and social needs of the chronically ill and should always be considered in relation to the family and community.

**Integrated approach**

It is now felt that the principles of prevention of CHD can be applied also to other major non-communicable diseases (NCDs) because of common risk factors. A broader concept is emerging, that is, to develop an overall integrated programme for the Prevention and Control of NCDs as part of primary health care systems, simultaneously attacking several risk factors known to be implicated in the development of non-communicable diseases. Such concerted preventive action should reduce not only cardiovascular diseases but also other major NCDs, with an overall improvement in health and length of life (14).

Recently, the WHO has developed a survey methodology known as "the STEPS Non-communicable Disease Risk Factors Survey" to help countries establish NCD surveillance system. Some surveys are conducted at the country level and others at the subnational level. The methodology prescribes three steps — questionnaire, physical measurements, and biochemical measurements. The core topics covered by most surveys are demographic, health status and health behaviours. These provide data on socio-economic risk factors and metabolic, nutritional and lifestyle risk factors. Details may differ from country to country and from year to year (15).

In India, the survey was conducted from April 2003 to March 2005 in 6 sites and again in 2007 in 7 states.

The Global Action Plan provides member states with a road map and menu of policy options which, when implemented collectively between 2013 and 2020, will contribute to progress on 9 global NCD targets including that of 25 per cent relative reduction in premature mortality from cardiovascular diseases, cancer, diabetes and chronic respiratory diseases by 2025. These four diseases make the largest contribution to mortality and morbidity due to NCDs. It will target four behavioural risk factors — tobacco use, unhealthy diet, physical inactivity and harmful use of alcohol. The voluntary global targets are (16):

1. A 25 per cent relative reduction in risk of premature mortality from cardiovascular diseases, cancer, diabetes and chronic respiratory disease.
2. At least 10 per cent relative reduction in the harmful use of alcohol as appropriate within national context.
3. A 10 per cent relative reduction in prevalence of insufficient physical activity;
4. A 10 per cent relative reduction in mean population intake of salt/sodium;
5. A 30 per cent relative reduction in prevalence of current tobacco use in persons aged 15 + years;
6. A 25 per cent relative reduction in prevalence of raised blood pressure;
7. Halts the rise of diabetes and obesity;
8. At least 50 per cent of eligible people receive drug therapy and counselling (including glycaemic control) to prevent heart attacks and strokes; and
9. An 80 per cent availability of the affordable basic technology and essential medicines including generics, required to treat major NCDs in both public and private facilities.

**2030 Agenda for Sustainable Development**

The Sustainable Development Goals include a specific target for NCDs and several NCD-related targets. Target 3.4 calls for a one third reduction in premature mortality from NCDs by year 2030 and is an extension of the global NCD mortality target. For further details, please refer to chapter 8.

CARDIOVASCULAR DISEASES

Cardiovascular diseases (CVD) comprise a group of diseases of the heart and the vascular system. The major conditions are ischaemic heart disease (IHD), hypertension, cerebrovascular disease (stroke) and congenital heart disease. Rheumatic heart disease (RHD) continues to be an important health problem in many developing countries.

Problem statement

WORLD

CVDs are the number one cause of death globally, more people die annually from CVD than any other cause. An estimated 17.7 million people died from CVD in 2015, representing 31 per cent of all global deaths. Of these global deaths, an estimated 7.4 million were due to coronary heart disease and 6.7 million were due to stroke (1). At least 82% of the world’s deaths from CVDs occur in low and middle-income countries, where people do not have the benefit of integrated primary health care programmes for early detection and treatment of risk factors compared to people in high-income countries. As a result, many cases in these countries are detected late in the course of the disease and die younger from CVDs and other NCDs, often in their most productive years. The poorest people are affected most. At the household level, CVD and other NCDs contribute to poverty due to catastrophic health spending and high out-of-pocket expenditure (2).

The incidence of CVD is greater in urban areas than in rural areas reflecting the acquisition of several risk factors such as tobacco consumption, lack of physical activity, unhealthy diet (today’s fast food habits) and obesity. A peculiar cause of concern is the relative early age of CVD deaths in the developing countries. Ironically CVDs are now in decline in the industrialized countries first associated with them. They seem to have crossed the peak of the epidemic by now. The decline is largely a result of the success of primary prevention and to a lesser extent, treatment. The middle and low-income countries are at the mid-point of the emerging epidemic and will face its full impact in the coming years. These countries can be benefitted from the strategy of primary prevention.

INDIA

An estimated 2.59 million people died of CVD in India during 2016, Table 1 shows the break-up of the cases and crude death rate per 100,000 population as reported to WHO.

Compared with all other countries, India suffers the highest loss in potentially productive years of life, due to deaths from CVD in people aged 35-64 years. The prevalence of CVD is reported to be 2-3 times higher in the urban population as compared to the rural population. In one study, the prevalence of IHD among adults (based on clinical and ECG criteria) was estimated at 96.7 per 1000 population in the urban and 27.1 per 1000 in rural areas (3).

The contribution of risk factors to the CVD have increased massively since last couple of decades. These risk factors are summarized in Table 2 (4).

Source: [4, 5]
dietary practices include a high consumption of saturated fats, salt and refined carbohydrates, as well as a low consumption of vegetables and fruits and these tend to cluster together.

Cessation of tobacco use, reduction of salt in the diet, consuming fruits and vegetables, regular physical activity and avoiding harmful use of alcohol have been shown to reduce the risk of cardiovascular disease. In addition, drug treatment of diabetes, hypertension and high blood lipids may be necessary to reduce cardiovascular risk and prevent heart attacks and strokes. Health policies that create conducive environment for making healthy choices affordable and available are essential for motivating people to adopt and sustain healthy behaviour.

There are also a number of underlying determinants of CVDs or "the causes of the causes". These are a reflection of the major forces driving social, economic and cultural change - globalization, urbanization and population ageing. Other determinants of CVDs include poverty, stress and hereditary factors.

Symptoms of heart attack and stroke

Often, there are no symptoms of the underlying disease of the blood vessels. A heart attack or stroke may be the first warning of underlying disease. Symptoms of a heart attack include:

- pain or discomfort in the centre of the chest; and
- pain or discomfort in the arms, the left shoulder, elbows, jaw, or back.

In addition, the person may experience difficulty in breathing or shortness of breath; feeling sick or vomiting; feeling light-headed or faint; breaking into a cold sweat; and becoming pale. Women are more likely to have shortness of breath, nausea, vomiting, and back or jaw pain.

The most common symptom of a stroke is sudden weakness of the face, arm, or leg, most often on one side of the body. Other symptoms include sudden onset of:

1. numbness of the face, arm, or leg, especially on one side of the body;
2. confusion, difficulty in speaking or understanding speech;
3. difficulty in seeing with one or both eyes;
4. difficulty in walking, dizziness, loss of balance or coordination;
5. severe headache with no known cause; and
6. fainting or unconsciousness.

People experiencing these symptoms should seek medical care immediately.

Symptoms of rheumatic heart disease include: shortness of breath, fatigue, irregular heart beats, chest pain and fainting. Symptoms of rheumatic fever include: fever, pain and swelling of the joints, nausea, stomach cramps and vomiting.

Interventions to reduce cardiovascular disease burden (3)

PRIMARY PREVENTION

The cost effective interventions that are feasible to be implemented include population-wide interventions and individual level interventions, which are recommended to be used in combination to reduce the CVDs.

The example of population-wide intervention are:

- comprehensive tobacco control policies;
- taxation to reduce the intake of foods that are high in fat, sugar and salt;
- building walking and cycle paths to increase physical activity;
- strategies to reduce harmful use of alcohol; and
- providing healthy school meals to children.

At the individual level, for prevention of first heart attacks and strokes, individual health-care interventions need to be targeted to those at high total cardiovascular risk or those with single risk factor level above traditional thresholds, such as hypertension and hypercholesterolemia. The former approach is more cost-effective than the later and has the potential to substantially reduce cardiovascular events. This approach is feasible in primary care in low-resource settings, including by non-physician health workers.

SECONDARY PREVENTION

For secondary prevention of cardiovascular disease in those with established disease, including diabetes, treatment with the following medications are necessary:

- aspirin;
- beta-blockers;
- angiotensin-converting enzyme inhibitors; and
- statins.

The benefits of these interventions are largely independent, but when used together with smoking cessation, nearly 75% of recurrent vascular events may be prevented. Currently there are major gaps in the implementation of these interventions particularly at the primary health care level.

In addition costly surgical operations are sometimes required to treat CVDs. They include:

- coronary artery bypass;
- balloon angioplasty (where a small balloon-like device is threaded through an artery to open the blockage);
- valve repair and replacement; and
- heart transplantation.

CORONARY HEART DISEASE

Coronary heart disease (syn: ischaemic heart disease) has been defined as "impairment of heart function due to inadequate blood flow to the heart compared to its needs, caused by obstructive changes in the coronary circulation to the heart" (1). It is the cause of 25–30 per cent of deaths in most industrialized countries. The WHO has drawn attention to the fact that CHD is our modern "epidemic", i.e., a disease that affects populations, not an unavoidable attribute of ageing. CHD may manifest itself in many presentations:

a. angina pectoris of effort
b. myocardial infarction
Measuring the burden of disease

The burden of CHD may be estimated in various ways, each illustrating a different aspect of the picture (3).

(a) Proportional mortality ratio: The simplest measure is the proportional mortality ratio, i.e., the proportion of all deaths currently attributed to it. For example, CHD is held responsible for about 30 per cent of deaths in men and 25 per cent of deaths in women in most western countries.

(b) Loss of life expectancy: CHD cuts short the life expectancy. Calculations have been made (4) for the average gain in life expectation that would follow a complete elimination of all cardiovascular deaths if other mortality rates remain unchanged. The benefit would range for men from 3.4 years to 9.4 years, and even greater for women.

(c) CHD incidence rate: This is the sum of fatal and non-fatal attack rates (5). Because of its different manifestations, accurate incidence of CHD rates are difficult to compute. Mortality rates can be used as a crude indicator of incidence.

(d) Age-specific death rates: When analysis is planned to throw light on aetiology, it is essential to study the age-specific rates. Age-specific death rates suggest a true increase in incidence.

(e) Prevalence rate: The prevalence of CHD can be estimated from cross-sectional surveys using ECG for evidence of infarction and history of prolonged chest pain. A useful publication to conduct such surveys is “Cardiovascular Survey Methods” by Rose and Blackburn (6).

(f) Case fatality rate: This is defined as the proportion of attacks that are fatal within 28 days of onset. The International Society and Federation of Cardiology has suggested that “sudden deaths” be defined to include deaths “occurring instantly or within an estimated 24 hours of the onset of acute symptoms or signs”. Data collected in many industrialized countries indicate that 25–28 per cent of patients who suffer a heart attack die suddenly. In about 55 per cent of all cardiac deaths mortality occurs within the first hour (7).

(g) Measurement of risk factor levels: These include measurement of levels of cigarette smoking, blood pressure, alcohol consumption and serum cholesterol in the community (8).

(h) Medical care: Measurement of levels of medical care in the community are also pertinent.

Epidemicity

“Epidemics” of CHD began at different times in different countries. In United States, epidemics began in the early 1920s (9); in Britain in the 1930s (10); in several European countries, still later. And now the developing countries are catching up. Countries where the epidemic began earlier are now showing a decline. For example, in United States, where the epidemic began in early 1920s, a steady decline was evident by 1968, and a 25 per cent fall in mortality (not morbidity) by 1980 (9). Substantial declines in mortality have also occurred in Australia, Canada and New Zealand.

The decline in CHD mortality in US and other countries has been attributed to changes in life-styles and related risk factors (e.g., diet and diet-dependent serum cholesterol, cigarette use and exercise habits) plus better control of hypertension (11).

The reasons for the changing trends in CHD are not precisely known. The WHO has completed a project known as MONICA (“multinational monitoring of trends and determinants in cardiovascular diseases”) to elucidate this issue. Forty-one centres in 26 countries were participating in this project, which was planned to continue for a 10 year period ending in 1994 (12).

When CHD emerged as the modern epidemic, it was the disease of the higher social classes in the most affluent societies. Fifty years later the situation is changing; there is a strong inverse relation between social class and CHD in developed countries (13).

To summarize, in many developed countries, CHD still poses the largest public health problem. But even in those showing a decline, CHD is still the most frequent single cause of death among men under 65 (13).

International variations

With 7.2 million deaths and 12.8 per cent of total deaths, CHD is a worldwide disease. Mortality rates vary widely in different parts of the world (Table 1).

Source: (14)

The highest coronary mortality is seen at present in the Western Pacific Region followed by European Region. On the other hand rates in Americas and Eastern Mediterranean countries are much lower.

Coronary heart disease in India

Coronary heart disease is assuming serious dimension in developing countries. There is a considerable increase in prevalence of CHD in urban areas in India during the last decade. Although there is increase in prevalence of CHD in rural areas also, but it is not that steep because life-style changes have affected people in urban areas more than in rural areas.

The pooled estimates from studies carried out in 1990s upto 2002 shows the prevalent rate of CHD in urban areas as 6.4 per cent and 2.5 per cent in rural areas. In urban areas the pooled estimate was 6.1 per cent for males and 6.7 per cent for females. In rural areas the estimate was...
2.1 per cent for males and 2.7 per cent for females (15). According to medical certification of cause of death data, 25.1 per cent of total deaths in urban areas are attributable to diseases of the circulatory system. Therefore, it was assumed that mortality rates due to CHD (which forms an important disease entity and the diseases of circulatory system) in rural areas are expected to be half of CHD specific mortality rates in urban areas.

It is estimated that 1,608,700 people died of CHD during 2016, of which 1,000,800 were men and 607,800 women. The crude death rate was 121.5/100,000 population (16).

Risk factors

The aetiology of CHD is multifactorial. Apart from the obvious ones such as increasing age and male sex, studies have identified several important “risk” factors (i.e., factors that make the occurrence of the disease more probable). Some of the risk factors are modifiable, others immutable (Table 2). Presence of any one of the risk factors places an individual in a high-risk category for developing CHD. The greater the number of risk factors present, the more likely one is to develop CHD. The principal risk factors are discussed below:

1. Smoking

Some people commit suicide by drowning, but many by smoking. A uniquely human habit, smoking has been identified as a major CHD risk factor (16, 17) with several possible mechanisms – carbon monoxide induced atherogenesis; nicotine stimulation of adrenergic drive raising both blood pressure and myocardial oxygen demand; lipid metabolism with fall in “protective” high-density lipoproteins, etc.

It has been calculated that in countries where smoking has been a widespread habit, it is responsible for 25 per cent of CHD deaths under 65 years of age in men (18). Cigarettes seem to be particularly important in causing sudden death from CHD especially in men under 50 years of age (18).

The degree of risk of developing CHD is directly related to the number of cigarettes smoked per day (20). Filter cigarettes are probably not protective (21). There is evidence that the influence of smoking is not only independent of, but also synergistic with other risk factors such as hypertension and elevated serum cholesterol (Fig. 1). This means that the effects are more than additive (18).

The risk of death from CHD decreases on cessation of smoking. The risk declines quite substantially within one year of stopping smoking and more gradually thereafter until, after 10–20 years, it is the same as that of non-smokers (18). For those who have had a myocardial infarction, the risk of a fatal recurrence may be reduced by 50 per cent after giving up smoking (18).

2. Hypertension

The blood pressure is the single most useful test for identifying individuals at a high risk of developing CHD. Hypertension accelerates the atherosclerotic process, especially if hyperlipidaemia is also present and contributes importantly to CHD. In the past, emphasis was placed on the importance of diastolic blood pressure. Many investigators feel that systolic blood pressure is a better predictor of CHD than is the diastolic. However, both components are significant risk factors. The risk role of “mild” hypertension is generally accepted (13).

3. Serum cholesterol

It is nearly three decades since it became clear that elevation of serum cholesterol was one of the factors which carried an increased risk for the development of myocardial infarction. Today, there is a vast body of evidence showing a triangular relationship between habitual diet, blood cholesterol–lipoprotein levels and CHD, and that these relationships are judged to be causal (1). There is no population, in which CHD is common, that does not also have a relatively high mean level of cholesterol (i.e., greater than 200 mg/dl in adults). This is illustrated in Fig 2 (1) which shows the cultural differences in serum cholesterol levels between two countries, Japan and Finland – Japan having the lowest incidence and Finland the highest incidence of CHD.
Coronary heart disease:

Fig. 2 shows that the risk of CHD rises steadily with the serum cholesterol concentration (22). The 14-year experience of the Seven Countries Study (23) showed that serum cholesterol concentration is an important risk factor for the incidence of CHD at levels perhaps 220 mg/dl or more. This supports the notion of a "threshold level" of cholesterol, that is, a certain level beyond which there is an association.

The strength of the dietary-fat hypothesis is that observations in the Seven Countries Study (among others) fitted it well — that is, the Japanese had low fat diets, low serum cholesterol and low incidence of CHD while the East Fins were at the other extreme (Fig. 2). The weakness of the hypothesis is that studies of individuals have not shown such a relationship. This has been attributed to genetic and dietary intake differences between individuals (1).

When we look at the various types of lipoproteins, it is the level of low-density lipoprotein (LDL) cholesterol that is most directly associated with CHD (24). While very low-density lipoprotein (VLDL) has also been shown to be associated with premature atherosclerosis, it is more strongly associated with peripheral vascular disease (e.g., intermittent claudication) than with CHD. High-density lipoprotein (HDL) cholesterol is protective against the development of CHD — the higher its mean level in a group of individuals, the lower the incidence of infarction in that group (25). HDL should be more than 40 mg dl.

To further refine CHD risk prediction based on serum lipid levels, a total "cholesterol/HDL ratio" has been developed. A ratio of less than 3.5 has been recommended as a clinical goal for CHD prevention (25).

With newer techniques, high-density and low-density lipoproteins have been further subdivided into sub-fractions. Recent evidence indicates that levels of plasma apolipoprotein-A-I (the major HDL protein) and apolipoprotein-B (the major LDL protein) are better predictors of CHD than HDL cholesterol or LDL cholesterol respectively. Therefore, measurement of apolipoproteins may replace lipoprotein cholesterol determinations in assessing the risk of CHD (26).

4. Other risk factors

(i) Diabetes: The risk of CHD is 2–3 times higher in diabetics than in non-diabetics. CHD is responsible for 30 to 50 per cent of deaths in diabetics over the age of 40 years in industrialized countries (27).

(ii) Genetic factors: A family history of CHD is known to increase the risk of premature death. Genetic factors are probably the most important determinants of a given individual's TC and LDL levels. However, the importance of genetic factors in the majority of cases is largely unknown.

(iii) Physical activity: Sedentary life-style is associated with a greater risk of the development of early CHD. There is evidence that regular physical exercise increases the concentration of HDL (28) and decreases both body weight and blood pressure which are beneficial to cardiovascular health.

(iv) Hormones: The pronounced difference in the mortality rates for CHD between male and female subjects (Table 3) suggests that the underlying factor may have a hormonal basis. It has been hypothesized that hyperestrogenemia may be the common underlying factor that leads both to atherosclerosis and its complications such as CHD, stroke and peripheral vascular disease (29).

(v) Type A personality: Type A behaviour is associated with competitive drive, restlessness, hostility and a sense of urgency or impatience. Type A individuals are more coronary prone to CHD than the calmer, more philosophical Type B individuals (30).

(vi) Alcohol: High alcohol intake, defined as 75 g or more per day is an independent risk factor for CHD, hypertension and all cardiovascular diseases (13). The evidence that moderate alcohol intake leads to a reduction in the risk of CHD is un-substantiated (31).

(vii) Oral contraceptives: Women using oral contraceptives have higher systolic and diastolic blood pressure. The risk of myocardial infarction in women seems to be increased by oral contraceptives, and the risk is compounded by cigarette smoking (32).

(viii) Miscellaneous: The possible role of dietary fibre, sucrose and soft water have been debated (5). Dyspnoea on exertion and low vital capacity have also been cited as possible risk factors.
PREVENTION OF CHD

In the 1960s the issue was whether CHD could be prevented or not. Studies were launched, reported and debated. The accumulated evidence led to a broad consensus of expert opinion that CHD is preventable (13). This is best expressed in a report of the WHO Expert Committee on the Prevention of CHD (1) which recommended the following strategies:

a. Population strategy
   (i) prevention in whole populations
   (ii) primary prevention in whole populations
b. High risk strategy
c. Secondary prevention.

Specific Interventions

The population strategy centres round the following key areas:

1. Dietary changes: Dietary modification is the principal preventive strategy in the prevention of CHD. The WHO Expert Committee (1) considered the following dietary changes to be appropriate for high incidence populations:
   - reduction of fat intake to 20–30 per cent of total energy intake
   - consumption of saturated fats must be limited to less than 10 per cent of total energy intake; some of the reduction in saturated fat may be made up by mono and poly-unsaturated fats
   - a reduction of dietary cholesterol to below 100 mg per 1000 kcal per day
   - an increase in complex carbohydrate consumption (i.e., vegetables, fruits, whole grains and legumes)
   - avoidance of alcohol consumption; reduction of salt intake to 5 g daily or less

2. Smoking: As far as CHD is concerned, present evidence does not support promotion of the so-called "safer cigarette" (13). The goal should be to achieve a smoke-free society, and several countries are progressing towards this goal.

   To achieve the goal of a smoke-free society, a comprehensive health programme would be required which includes effective information and education activities, legislative restrictions, fiscal measures and smoking cessation programmes.

3. Blood pressure: It has been estimated that even a small reduction in the average blood pressure of the whole population by a mere 2 or 3 mm Hg would produce a large reduction in the incidence of cardiovascular complications (34, 35). The goal of the population approach to high blood pressure would thus be to reduce mean population blood pressure levels. This involves a multifactorial approach based on a "prudent diet" (reduced salt intake and avoidance of a high alcohol intake), regular physical activity and weight control. The potential benefits and the safety and low cost of this advice would justify its implementation.

4. Physical activity: Regular physical activity should be a part of normal daily life. It is particularly important to encourage children to take up physical activities that they can continue throughout their lives (1).

PRIMORDIAL PREVENTION

A novel approach to primary prevention of CHD is primordial prevention (1). It involves preventing the emergence and spread of CHD risk factors and life-styles that have not yet appeared or become endemic. This applies to developing countries in particular. These countries should seek to preserve their traditional eating patterns and life-styles associated with low levels of CHD risk factors.

Since the aetiology of CHD is multifactorial the approach to prevention should be multifactorial aimed at controlling or modifying as many risk factors as possible. The aim should be to change the community as a whole, not the individual subjects living in it (36).

Several well-planned risk factor intervention trials (e.g., the Multiple Risk Factor Intervention Trial (MRFIT) in the US (37), the Stanford Heart Disease Prevention Programme in California (38), and The North Kerelia Project in Finland (39) have demonstrated that primary prevention can achieve substantial reduction in the incidence of coronary heart disease. For detailed information, the reader is referred to references 37, 38 and 39.

b. High risk strategy

(i) Identifying risk: High-risk intervention can only start once those at high risk have been identified. By means of simple tests such as blood pressure and serum cholesterol measurement it is possible to identify individuals at special risk (1). Individuals at special risk also include those who smoke, those with a strong family history of CHD, diabetes and obesity and young women using oral contraceptives.

(ii) Specific advice: Having identified those at high risk, the next step will be to bring them under preventive care and motivate them to take positive action against all the identified risk factors, e.g., an elevated blood pressure should be treated; the patient should be helped to break the smoking habit permanently — nicotine chewing gum can be tried to wean patients from smoking (40); serum cholesterol concentration should be reduced in those in whom it is raised, etc.

Several well-planned high-risk intervention studies (e.g., Oslo Heart Study (41), Lipid Research Clinics Study (42), in US have shown that it is feasible to reduce the CHD risk factors.

From a methodological point of view, however, high-risk approach suffers from the disadvantage that the intervention (e.g., treatment) may be effective in reducing the disease in a high-risk group, but it may not reduce the disease to the same extent in the general population which consists of symptomatic, asymptomatic, high-risk, low-risk and healthy people (43). Further, unfortunately, more than half of the CHD cases occur in those who are not apparently at special risk, and this is one limitation of the high-risk strategy (1). Nevertheless, recognition and treatment of high-risk cases do make an important contribution to prevention (1).
c. Secondary prevention

Secondary prevention must be seen as a continuation of primary prevention. It forms an important part of an overall strategy. The aim of secondary prevention is to prevent the recurrence and progression of CHD. Secondary prevention is a rapidly expanding field with much research in progress (e.g., drug trials, coronary surgery, use of pace makers).

The principles governing secondary prevention are the same as those already set out in the above sections, e.g., cessation of smoking, control of hypertension and diabetes, healthy nutrition, exercise promotion, etc. The most promising results to date appear to reduce the risk of CHD mortality in patients who have already suffered at least one infarct in the order of 25 per cent. None of the preventive measures discussed earlier lose their importance even after the first attack. For example, cessation of smoking is the most effective single means of intervention currently available in the management of patients after a heart attack. The risk of fatal infarction or sudden death is reduced by 20-50 per cent. If the patient does not stop smoking, nothing else is worth doing (44).

Despite advances in treatment, the mortality of an acute heart attack is still high: among survivors, around 10 per cent in the first year, and 5 per cent yearly thereafter. Delay in reaching hospital is still considerable even in big cities in the West and may be as much as 3.5 hours. About 30 per cent of all deaths occur within 30 minutes of onset. This is one of the reasons why coronary care units have failed to make impact on the total coronary mortality in the community (45, 46).

Each strategy — population strategy, high-risk strategy, secondary prevention — has its advantages and disadvantages, but the population strategy has the greatest potential.

Revascularization procedures for patients with angina pectoris (47)

The indications for coronary artery revascularization i.e. coronary artery bypass grafting (CABG) and percutaneous transluminal coronary angioplasty (PTCA) in patients with angina pectoris are often debated. There is general agreement that otherwise healthy patients in the following groups should undergo revascularization, (a) patients with unacceptable symptoms despite medical therapy to its tolerable limits; (b) patients with left main coronary artery stenosis greater than 50 per cent with or without symptoms; (c) patients with three-vessel disease with left ventricular dysfunction (ejection fraction <50 per cent or previous transmural infarction); (d) patients with unstable angina who after symptom control by medical therapy continue to exhibit ischaemia on exercise testing or monitoring and (e) post-myocardial infarction patients with continuing angina or severe ischaemia on noninvasive testing.

CABG can be accomplished with a very low mortality rate (1-3 per cent) in otherwise healthy patients with preserved cardiac function. However, the mortality rate of this procedure rises to 4-8 per cent in older individuals and in patients who have had a prior CABG. Increasingly, younger individuals with focal lesions of one or more vessels are undergoing coronary angioplasty as the initial revascularization procedure, where coronary artery stenosis can be effectively dilated by inflation of a balloon under high pressure. PTCA is also possible but less successful in bypass graft stenosis.

The incidence of restenosis appears to be reduced with intracoronary stent placement and may be as low as 15-20 per cent. The number of PTCA and stent procedure now exceeds that of CABG operations. Several studies have shown PTCA to be superior to medical therapy for symptom relief but not in preventing infarction or death. In patients with no or only mild symptoms, aggressive lipid-lowering and anti-anginal therapy may be preferable to PTCA.

RISK FACTOR INTERVENTION TRIALS

Since 1951, one of the best known large prospective studies, the Framingham Study, has played a major role in establishing the nature of CHD risk factors and their relative importance (48, 49). The major risk factors of CHD are elevated serum cholesterol, smoking, hypertension and sedentary habits. Accordingly, the four main possibilities of intervention in CHD prevention are: reduction of serum cholesterol, the cessation of smoking, control of hypertension and promotion of physical activity.

Risk factor trials can be "single factor" trials or "multi-factor" trials. Both the approaches are complementary and both are needed. Early trials of CHD prevention concentrated on one factor (e.g., dietary cholesterol). Later emphasis swung away from unifactorial to multifactorial approach.

The widely reported intervention trials are: (a) The Stanford Heart Disease Prevention Programme in California, (b) The North Kerelia Project in Finland, (c) The Oslo Study, (d) The Multiple Risk Factor Intervention Trial (MRFIT) in USA, and (e) The Lipid Research Clinics Study. A brief account of these trials is given below. For more details the reader is referred to the references cited in the text.

1. The Stanford–Three–Community Study (38).

To determine whether community health education can reduce the risk of cardiovascular disease, a field experiment was undertaken in 1972 in three northern California towns with populations varying between 12,000 and 15,000. In two of these towns intensive mass education campaigns were conducted against cardiovascular risk factors over a period of 2 years. The third community served as a control. People from each community were interviewed and examined before the campaign began and one and two years afterwards to assess knowledge and behaviour related to cardiovascular diseases (e.g., diet and smoking) and also to measure physiological indicators of risk (e.g., blood pressure, serum cholesterol, relative weight). In the control community, the risk of cardiovascular disease increased over the two years, but in the intervention communities there was a substantial and sustained decrease in risk. The net difference in estimated total risk between control and intervention samples was 23–28 per cent.

2. The North Kerelia Project (36, 39)

North Kerelia is a county in the eastern part of Finland, where CHD is particularly common. Its 185,000 inhabitants work mostly in farming and forestry and live in the countryside.

A multiple risk factor intervention trial started in 1972. The project had two aims: (a) to reduce the high levels of risk factors for cardiovascular disease (e.g., smoking, blood pressure and serum cholesterol), and (b) to promote the early diagnosis, treatment and rehabilitation of patients with CV disease. A control population was established in a neighbouring county which has similar CV mortality. The main strategy employed was mass community action against risk factors and advice on their avoidance.
Follow-up surveys at 5-years demonstrated a significant reduction in all three major risk factors. By 1979, mortality began to decline by 24 per cent in men and 51 per cent in women in North Karelia, compared with 12 per cent in men and 26 per cent in women in rest of Finland. A further representative sample (8000) was studied in 1982. It exhibited its effect on CHD deaths—more than twice the reduction achieved in the rest of Finland during the same period. Thus it took 10 years (Rose's 10-year incubation period) to exhibit its effect on CHD deaths.

3. MRFIT (37)

The multiple risk factor intervention trial (MRFIT) carried out in USA was aimed at high risk adult males aged 35-57 years. A total of 12,866 men who showed no evidence of CHD either clinically or on ECG were enrolled for the study. Half the group was randomly allocated to an intensive intervention programme, being seen at least every four months to ensure adequate control of risk factors. The other half (control group) received a medical examination once yearly, and no specific advice was given to them about the control of risk factors. The intervention procedures included cessation of smoking, controlling blood pressure and altering diet to reduce hypercholesterolaemia.

Over the 7 year follow-up period, IHD mortality was reduced by 22 per cent more in the intervention group but this was not statistically significant. This was because the control group had also changed their habits and lifestyle to a far greater extent than anticipated by the designers of the trial. The trial produced no significant changes at all in mortality or risk factors in as much as the control group was not properly chosen.

4. Oslow diet/smoking Intervention Study (41)

This study began in 1973. 16,202 Norwegian men aged 40-49 years were screened for coronary risk factors: of these 1232 healthy normotensive men at high risk (total serum cholesterol 290-379 mg/dl; smoking) of CHD were selected for a 5 year randomized trial. The aim of the study was to determine whether lowering of serum lipids and cessation of smoking would reduce the incidence of first attack of CHD in males aged 40-50.

The intervention group underwent techniques designed to lower serum cholesterol level through dietary means (e.g., a polyunsaturated fat diet), and to decrease or eliminate smoking. At the end of 5 years, the incidence of myocardial infarction (fatal and nonfatal) was lower by 47 per cent in the intervention group than in the control group.

With this study, primary prevention of CHD entered the practical field of preventive medicine in an impressive manner.

5. Lipid Research Clinics Study (42)

This double-blind, randomized clinical trial involved 3806 asymptomatic “high-risk” American men aged 35-59 years with type II hyperlipoproteinaemia. The trial was designed to test whether reducing serum cholesterol would prevent CHD events.

The men were randomized into two groups, one receiving cholestyramine and the other receiving a placebo. Both the groups were followed for an average of 7.4 years.

The treatment group had an 8.5 per cent and 12.6 per cent greater reduction in total cholesterol and LDL-cholesterol levels respectively than the placebo-treated group. This difference resulted in a 24 per cent reduction in non-fatal myocardial infarction. The findings of this study have resulted in enthusiasm for the drug treatment of those men with considerably elevated serum cholesterol levels.

Secondary prevention trials

Secondary prevention trials are aimed at preventing a subsequent coronary attack or sudden death. A wide range of clinical trials have been performed with four main groups of drugs—anti-coagulants, lipid-lowering agents (e.g., clofibrate), anti-thrombotic agents (e.g., aspirin) and beta-blockers. The most promising results to date have come from beta blockers.

In general the above studies and similar others show that it is feasible through well-planned intervention programmes to reduce the risk factors in the populations studied. The primary and secondary prevention studies promise at present to be the main contribution of epidemiology to the conquest of chronic diseases.

References

HYPERTENSION

Hypertension is a chronic condition of concern due to its role in the causation of coronary heart disease, stroke and other vascular complications. It is the commonest cardiovascular disorder, posing a major public health challenge to population in socio-economic and epidemiological transition. It is one of the major risk factors for cardiovascular mortality, which accounts for 20-50 per cent of all deaths.

Definition of hypertension is difficult and, by necessity, arbitrary. Sir George Peckering first formulated a concept that blood pressure in a population is distributed continuously as a bell-shaped curve with no real separation between normotension and hypertension (1). There is also a direct relation between cardiovascular risk and blood pressure: the higher the blood pressure, the higher the risk of both stroke and coronary events (1). As a consequence, the dividing line between normal and high blood pressure can be defined only in an operational way.

As intervention trials included only adults aged 18 years or older, definition and classification of hypertension refer to adults not taking anti-hypertensive drugs and not actually ill, and based on the average of two or more readings on two or more occasions after initial screening. Table 1 shows the classification of hypertension by blood pressure level.

When systolic and diastolic blood pressure fall into different categories, the higher category should be selected to classify the individual's blood pressure. "Isolated systolic hypertension" is defined as a systolic blood pressure of 140 mm of Hg or more and a diastolic blood pressure of less than 90 mm of Hg.

Organ damage

Although the extent of organ damage often correlates with the level of blood pressure, it is not always the case. In addition the rate of progression of organ damage varies from one individual to another depending on many influences, most of which are incompletely understood. Therefore, blood pressure and organ impairment should be evaluated separately, since markedly high pressures may be seen without organ damage and, conversely, organ damage may be present with only moderate elevation of blood pressure. The presence of signs of organ damage confers an increased cardiovascular risk to any level of blood pressure.

Blood pressure measurement

Despite more than 75 years of experience with the measurement of blood pressure, discussion continues about its reliability and wide variability in individual subjects. Accurate measurements are essential under standardized conditions for valid comparison between persons or groups over time. Three sources of errors have been identified in the recording of blood pressure: (a) Observer errors: e.g., hearing acuity, interpretation of Korotkow sounds. (b) Instrumental errors: e.g., leaking valve, cuffs that do not encircle the arm. If the cuff is too small and fails to encircle the arm properly then too high a reading will be obtained; and (c) Subject errors: e.g., the circumstances of examination. These include the physical environment, the position of the subject, external stimuli such as fear, anxiety, and so on (3).

A few salient points need be mentioned about measuring blood pressure. A WHO Study Group (4) recommended the sitting position instead of the supine position for recording blood pressure. In any clinic a uniform policy should be adopted, using either the right or left arm consistently. The pressure at which the sounds are first heard (phase I) is taken to indicate the systolic pressure. Near the diastolic pressure the sounds first become muffled (phase IV) and then disappear (phase V). Most of the studies have used phase V to measure diastolic blood pressure. The systolic and diastolic pressures should be measured at least three times over a period of at least 3 minutes and the lowest reading recorded. For reasons of comparability, the data should be recorded everywhere in a uniform way.

Classification

Hypertension is divided into primary (essential) and secondary. Hypertension is classified as "essential" when the causes are generally unknown. Essential hypertension is the most prevalent form of hypertension accounting for 90 per cent of all cases of hypertension. Hypertension is classified as "secondary" when some other disease process or abnormality is involved in its causation. Prominent among these diseases are diseases of kidney (chronic glomerulonephritis and chronic pyelonephritis), tumours of the adrenal glands, congenital narrowing of the aorta and toxemias of pregnancy. Altogether, these are estimated to account for about 10 per cent or less of the cases of hypertension.

Magnitude of the problem

Although blood pressure is easily measured, it had taken several decades to realise that arterial hypertension is a frequent, worldwide health disorder (5). "Rule of halves"

Hypertension is an "iceberg" disease. It became evident in the early 1970s that only about half the hypertensive subjects in the general population of most developed
The areas of the circles shown in Fig. 1 correspond to the actual proportions observed in several population based studies and number-wise represent the following: (6).

1. The whole community
2. Normotensive subjects
3. Hypertensive subjects
4. Undiagnosed hypertension
5. Diagnosed hypertension
6. Diagnosed but untreated
7. Diagnosed and treated
8. Inadequately treated
9. Adequately treated

INCIDENCE: The concept of incidence has limited value in hypertension because of the variability of consecutive readings in individuals, ambiguity of what is “normal” blood pressure and the insidious nature of the condition (8).

The global prevalence of hypertension was estimated to be 1.13 billion in 2015. The overall prevalence of hypertension in adults is around 30-40 per cent, with a global age standardized prevalence of 24 and 20 per cent in men and women respectively. This high prevalence of hypertension across the world is irrespective of income status i.e., in lower, middle and higher income countries. Hypertension becomes progressively more common with advancing age, with a prevalence of >60 per cent in people aged >60 years. As populations age, they adopt more sedentary life styles and increase in their body weight. It is estimated that the number of people with hypertension will increase by 15-20 per cent by year 2025 (2). Elevated blood pressure is a leading cause of premature death in 2015, accounting to almost 10 million deaths and over 200 million DALYs. Despite advances in diagnosis and treatment over the past 30 years, the DALYs have increased by 40 per cent since 1990. Systolic blood pressure $\geq$140 mmHg accounts for most of the mortality and disability burden. The largest number of systolic blood pressure related deaths per year are due to IHD (4.9 million), haemorrhagic stroke (2 million) and ischaemic stroke (1.5 million) (2).

Prevalence in India

In the year 2015-2016, National Family Health Survey-4 measured blood pressure in women and men aged 15-49 years. The criteria of high blood pressure was systolic blood pressure $\geq$140 mmHg and diastolic blood pressure $\geq$90 mmHg. or. that individual is currently taking antihypertensive medicine. Based on the measurement during the survey, 11 per cent of women were having hypertension (7 per cent with stage 1 hypertension and one per cent each of with stage 2 and 3 hypertension), 61 per cent of women were having blood pressure within normal limits, almost 30 per cent were prehypertensive and 1 per cent were taking anti-hypertensives.

The prevalence of hypertension among men aged 15-49 years was somewhat higher than among women, 15 per cent men were hypertensive (10 per cent with stage 1, 2 per cent with stage 2 and 1 per cent with stage 3 hypertension) 43 per cent men had normal blood pressure and same percentage were prehypertensive. One per cent were on anti-hypertensive medicines. For both men and women, the prevalence of hypertension increased with age.

The prevalence of hypertension is higher among Sikhs (24 per cent for men and 16 per cent for women), Jains 19 per cent for men and 16 per cent for women and Buddhist/ Neo-Buddhist men 19 per cent, than the rest of the religion groups (8). There is a consistent increase in prevalence of hypertension with increase in body mass index, for both men and women. 29 per cent of obese women and 38 per cent of obese men were hypertensive. The prevalence of hypertension among women at 15-49 years ranges from 8 per cent in Bihar to 18 per cent in Sikkim and Assam. For men, the prevalence ranges from 5 per cent in Delhi to 31 per cent in Sikkim. For both men and women, the North-eastern states (except Meghalaya for men) have a higher prevalence than the national average (8).

“Tracking” of blood pressure

If blood pressure levels of individuals were followed up over a period of years from early childhood into adult life, then those individuals whose pressures were initially high in the distribution, would probably continue in the same “track” as adults. In other words, low blood pressure levels tend to remain low, and high levels tend to become higher as individuals grow older. This phenomenon of persistence of rank order of blood pressure has been described as “tracking” (9). This knowledge can be applied in identifying children and adolescents “at risk” of developing hypertension at a future date.
Risk factors for hypertension

Hypertension is not only one of the major risk factors for most forms of cardiovascular disease, but that it is a condition with its own risk factors. A WHO Scientific Group (5) has recently reviewed the risk factors for essential hypertension. These may be classified as:

1. Non-modifiable risk factors

(a) AGE: Blood pressure rises with age in both sexes and the rise is greater in those with higher initial blood pressure. Age probably represents an accumulation of environmental influences and the effects of genetically programmed senescence in body systems (3). Some populations have now been identified whose mean blood pressure does not rise with age (10). These communities are for the most part primitive societies with calorie and salt intakes at subsistence level.

(b) SEX: Early in life there is little evidence of a difference in blood pressure between the sexes. However, at adolescence, men display a higher average level. This difference is more evident in young and middle aged adults. Late in life the difference narrows and the pattern may even be reversed (1). Post-menopausal changes in women may be the contributory factor for this change. Studies are in progress to evaluate whether oestrogen supplementation protects against the late relative rise of blood pressure in women (1).

(c) GENETIC FACTORS: There is considerable evidence that blood pressure levels are determined in part by genetic factors, and that the inheritance is polygenic. The evidence is based on twin and family studies. Twin studies have confirmed the importance of genetic factors in hypertension. The blood pressure values of monozygotic twins are usually more strongly correlated than those of zygotic twins. In contrast, no significant correlation has been noted between their adoptive parents (5).

Family studies have shown that the children of two normotensive parents have 3 per cent possibility of developing hypertension, whereas this possibility is 45 per cent in children of two hypertensive parents (11). Blood pressure levels among first degree adult relatives have also been noted to be statistically significant (5).

Attempts to find genetic markers that are associated with hypertension have been largely unsuccessful. The detailed mechanism of heredity, i.e., how many genes and loci are involved and their mode of inheritance have not yet been conclusively elucidated.

(d) ETHNICITY: Population studies have consistently revealed higher blood pressure levels in black communities than other ethnic groups (1). Average difference in blood pressure between the two groups vary from slightly less than 5 mm Hg during the second decade of life to nearly 20 mm Hg during the sixth. Black Americans of African origin have been demonstrated to have higher blood pressure levels than whites.

2. Modifiable risk factors

(a) OBESITY: Epidemiological observations have identified obesity as a risk factor for hypertension (12). The greater the weight gain, the greater the risk of high blood pressure. Data also indicate that when people with high blood pressure lose weight, their blood pressure generally decreases. "Central obesity" indicated by an increased waist to hip ratio, has been positively correlated with high blood pressure in several populations.

(b) SALT INTAKE: There is an increasing body of evidence to the effect that a high salt intake (i.e., 7-8 g per day) increases blood pressure proportionally. Low sodium intake has been found to lower the blood pressure (13). For instance, the higher incidence of hypertension is found in Japan where sodium intake is above 400 mmol/day while primitive societies ingesting less than 60 mmol/day have virtually no hypertension (14). It has been postulated that essential hypertensives have a genetic abnormality of the kidney which makes salt excretion difficult except at raised levels of arterial pressure (5).

Besides sodium, there are other mineral elements such as potassium which are determinants of blood pressure. Potassium antagonizes the biological effects of sodium, and thereby reduces blood pressure. Potassium supplements have been found to lower blood pressure of mild to moderate hypertensives. Other cations such as calcium, cadmium and magnesium have also been suggested as of importance in reducing blood pressure levels.

(c) SATURATED FAT: The evidences suggest that saturated fat raises blood pressure as well as serum cholesterol (15). For further details refer to chapter 11.

(d) DIETARY FIBRE: Several studies indicate that the risk of CHD and hypertension is inversely related to the consumption of dietary fibre. Most fibres reduce plasma total and LDL cholesterol (1).

(e) ALCOHOL: High alcohol intake is associated with an increased risk of high blood pressure. It appears that alcohol consumption raises systolic pressure more than the diastolic. But the finding that blood pressure returns to normal with abstinence suggests that alcohol-induced elevations may not be fixed, and do not necessarily lead to sustained blood pressure elevation (3).

(f) HEART RATE: When groups of normotensive and untreated hypertensive subjects, matched for age and sex, are compared, the heart rate of the hypertensive group is invariably higher. This may reflect a resetting of sympathetic activity at a higher level. The role of heart variability in blood pressure needs further research to elucidate whether the relation is casual or prognostic (1).

(g) PHYSICAL ACTIVITY: Physical activity by reducing body weight may have an indirect effect on blood pressure.

(h) ENVIRONMENTAL STRESS: The term hypertension itself implies a disorder initiated by tension or stress. Since stress is nowhere defined, the hypothesis is untestable (3). However, it is an accepted fact that psychosocial factors operate through mental processes, consciously or unconsciously, to produce hypertension. Virtually all studies on blood pressure and catecholamines levels in young people revealed significantly higher norepinephrine levels in hypertensives than in normotensives. This supports the contention that over-activity of the sympathetic nervous system has an important part to play in the pathogenesis of hypertension (9).

(i) SOCIO-ECONOMIC STATUS: In countries that are in post-transitional stage of economic and epidemiological change, consistently higher levels of blood pressure have been noted in lower socio-economic groups. This inverse relation has been noted with levels of education, income and occupation. However, in societies that are transitional or pre-transitional, a higher prevalence of hypertension has been noted in upper socio-economic groups. This probably represents the initial stage of the epidemic of CVD (1).
NON-COMMUNICABLE DISEASES

(j) OTHER FACTORS: The commonest present cause of secondary hypertension is oral contraception, because of the oestrogen component in combined preparations. Other factors such as noise, vibration, temperature and humidity require further investigation (5).

PREVENTION OF HYPERTENSION

The low prevalence of hypertension in some communities indicates that hypertension is potentially preventable (16). The WHO has recommended the following approaches in the prevention of hypertension:

1. Primary prevention
   (a) Population strategy
   (b) High-risk strategy
2. Secondary prevention

1. PRIMARY PREVENTION

Although control of hypertension can be successfully achieved by medication (secondary prevention) the ultimate goal in general is primary prevention. Primary prevention has been defined as "all measures to reduce the incidence of disease in a population by reducing the risk of onset" (17). The earlier the prevention starts the more likely it is to be effective.

In connection with primary prevention, terms such as "population strategy" and "high-risk strategy" have become established (5, 18). The WHO has recommended these approaches in the prevention of hypertension. Both the approaches are complementary.

a. POPULATION STRATEGY

The population approach is directed at the whole population, irrespective of individual risk levels. The concept of population approach is based on the fact that even a small reduction in the average blood pressure of a population would produce a large reduction in the incidence of cardiovascular complications such as stroke and CHD (16). The goal of the population approach is to shift the community distribution of blood pressure towards lower levels or "biological normality" (9). This involves a multifactorial approach, based on the following non-pharmacotherapeutic interventions:

   (a) NUTRITION: Dietary changes are of paramount importance. These comprise: (i) reduction of salt intake to an average of not more than 5 g per day (ii) moderate fat intake (iii) the avoidance of a high alcohol intake, and (iv) restriction of energy intake appropriate to body needs.
   (b) WEIGHT REDUCTION: The prevention and correction of over weight/obesity (Body Mass Index greater than 25) is a prudent way of reducing the risk of hypertension and indirectly CHD; it goes with dietary changes.
   (c) EXERCISE PROMOTION: The evidence that regular physical activity leads to a fall in body weight, blood lipids and blood pressure goes to suggest that regular physical activity should be encouraged as part of the strategy for risk-factor control.
   (d) BEHAVIOURAL CHANGES: Reduction of stress and smoking, modification of personal life-style, yoga and transcendental meditation could be profitable.
   (e) HEALTH EDUCATION: The general public require preventive advice on all risk factors and related health behaviour. The whole community must be mobilized and made aware of the possibility of primary prevention, and (f) SELF-CARE: Reducing stress and smoking, modification of personal life-style, yoga and transcendental meditation could be profitable.

In connection with primary prevention, terms such as "population strategy" and "high-risk strategy" have become established (5, 18). The WHO has recommended these approaches in the prevention of hypertension. Both the approaches are complementary.

b. HIGH-RISK STRATEGY

This is also part of primary prevention. The aim of this approach is "to prevent the attainment of levels of blood pressure at which the institution of treatment would be considered" (3). This approach is appropriate if the risk factors occur with very low prevalence in the community (3).

Detection of high-risk subjects should be encouraged by the optimum use of clinical methods. Since hypertension

tends to cluster in families, the family history of hypertension and “tracking” of blood pressure from childhood may be used to identify individuals at risk.

2. SECONDARY PREVENTION

The goal of secondary prevention is to detect and control high blood pressure in affected individuals. Modern antihypertensive drug therapy can effectively reduce high blood pressure and consequently, the excess risk of morbidity and mortality from coronary, cerebrovascular and kidney disease. The control measures comprise:

(i) EARLY CASE DETECTION: Early detection is a major problem. This is because high blood pressure rarely causes symptoms until organ damage has already occurred, and our aim should be to control it before this happens. The only effective method of diagnosis of hypertension is to screen the population. But screening, that is not linked to follow-up and sustained care, is a fruitless exercise. It is emphasized that screening should not be initiated if health resources for treatment and follow-up are not adequate.

In the developed countries, mass screening is not considered essential for the adequate control of blood pressure in the population. In Europe, the large majority of people have at least one contact in every 2 years with the health service. If blood pressure is measured at each such contact, the bulk of the problem of detecting those in need of intervention is solved.

(ii) TREATMENT: In essential hypertension, as in diabetes, we cannot treat the cause, because we do not know what it is. Instead, we try to scale down the high blood pressure to acceptable levels. The aim of treatment should be to obtain a blood pressure below 140/90, and ideally a blood pressure of 120/80. Control of hypertension has been shown to reduce the incidence of stroke and other complications. This is a major reason for identifying and treating asymptomatic hypertension. Care of hypertensives should also involve attention to other risk factors such as smoking and elevated blood cholesterol levels (16).

(iii) PATIENT COMPLIANCE: The treatment of high blood pressure must normally be life-long and this presents problems of patient compliance, which is defined as “the extent to which patient behaviour (in terms of taking medicines, following diets or executing other lifestyle changes) coincides with clinical prescription”. The compliance rates can be improved through education directed to patients, families and the community.

Intensive research carried out during the past decade, aiming at control of hypertension at the community level, has already provided valuable results. The studies have shown that control of hypertension in a population is feasible, that it can be carried out through the existing system of health services in different countries, and that the control of blood pressure leads to a reduction of complications of high blood pressure — namely stroke, heart failure and renal failure. In some of the projects the incidence of myocardial infarction was also reduced. As a result of these findings, some countries have launched nationwide control programmes in the field of hypertension (21).

STROKE

The term “stroke” (syn : apoplexy) is applied to acute severe manifestations of cerebrovascular disease. It causes both physical and mental crippling, WHO defined stroke as “rapidly developed clinical signs of focal disturbance of cerebral function; lasting more than 24 hours or leading to death, with no apparent cause other than vascular origin” (11). The 24 hours threshold in the definition excludes transient ischaemic attacks (TIA) which is defined to last less than 24 hours, and patients with stroke symptoms caused by subdural haemorrhage, tumours, poisoning or trauma are excluded.

The disturbance of cerebral function is caused by three morphological abnormalities, i.e., stenosis, occlusion or rupture of the arteries. Dysfunction of the brain (“neurological deficit”) manifests itself by various neurological signs and symptoms that are related to extent and site of the area involved and to the underlying causes. These include coma, hemiplegia, paraplegia, monoplegia, multiple paralysis, speech disturbances, nerve paresis, sensory impairment, etc. Of these hemiplegia constitutes the main somatoneurological disorder in about 90 per cent of patients (2)

Stroke includes a number of syndromes with differing aetiologies, epidemiology, prognosis and treatment. These are listed below:

A. Ischaemic stroke
   a. Lacunar Infarct
   b. Carotid circulation obstruction
   c. Vertebro-basilar obstruction

B. Haemorrhagic stroke
   a. Spontaneous intracerebral haemorrhage
   b. Subarachnoid haemorrhage
   c. Intracranial aneurysm
   d. Arteriovenous malformations.

Problem

Stroke is a worldwide health problem. It makes an important contribution to morbidity, mortality and disability in developed as well as developing countries. Although there are substantial differences in frequency from place to place, cerebral thrombosis is usually the most frequent form of stroke encountered in clinical studies, followed by
haemorrhage. Subarachnoid haemorrhage and cerebral embolism come next as regards both mortality and morbidity (2). However, stroke from cerebral haemorrhage is more common in Japan than elsewhere (1).

MORBIDITY AND MORTALITY

Cerebrovascular disease remain a leading cause of death from NCDs. In 2016 it was estimated that cerebrovascular disease accounted for 5.78 million deaths worldwide, equivalent to 10.2 per cent of all deaths. Majority of these deaths occurred in people living in developing countries and 33.72 per cent of the subjects were aged less than 70 years (3). Additionally, cerebrovascular disease is the leading cause of disability in adults and each year millions of stroke survivors have to adopt life with restriction in activities of daily living as a consequence of stroke. Many surviving stroke patients will often depend on other people’s continuous support to live (4).

In demographically developed countries, the average age at which stroke occurs is around 73 years reflecting the older age structure of these countries. The probability of a first stroke or first TIA is around 1.6 per 1000 and 0.42 per 1000 respectively. In less developed regions, the average age of stroke is less due to the different population age structure, resulting from higher mortality rates.

Stroke patients are at highest risk of death in the first weeks after the event, and between 20–50 per cent die within first month depending on type, severity, age, co-morbidity and effectiveness of treatment of complications. Patients who survive may be left with no disability or with mild, moderate or severe disability. Considerable spontaneous recovery occurs up to 6 months. However, patients with history of stroke are at high risk of a subsequent event of around 10 per cent in the first year and 5 per cent year thereafter (4).

The proportion of patients achieving independence in self-care by one year after a stroke range from around 60 to 83 per cent. This depends on whether the studies are community-based or hospital-based, which activity is considered in estimating independence, and the methods used to rate ability (4).

There is evidence that mortality from stroke has been declining in many countries for several years. Some of the decline occurred before modern treatment methods became available, indicating that the decline in stroke was associated with social and economic changes.

INDIA

Although the prevalence of stroke appears to be comparatively less in India than in developed countries, it is likely to increase proportionally with the increase in life expectancy. The proportion of stroke in the young population is significantly more in India than in developed countries; some of the more important causes for this are likely to be rheumatic heart disease, ischaemic strokes in peripartum period and arteriopathies as a sequel of CNS infections like bacterial and tubercular meningitis etc. (5).

In India 0.706 million people died of stroke in 2016 of which 0.372 million were men and 0.334 million were women. The crude death rate of stroke was about 54.2 per 100,000 population (3).

1. RISK FACTORS

Epidemiological studies have indicated that stroke does not occur at random, and there are factors (risk factors) which precede stroke by several years. These are: (a) Hypertension: This is considered the main risk factor for cerebral thrombosis as well as cerebral haemorrhage; (b) Other factors: Additional factors contributing to risk are cardiac abnormalities (i.e., left ventricular hypertrophy, cardiac dilatation), diabetes, elevated blood lipids, obesity, smoking, glucose intolerance, blood clotting and viscosity, oral contraceptives, etc. The importance of these factors is not clearly defined. Although the risk factors for stroke are similar to those for CHD, their relative importance differs (6).

2. TRANSCIENT ISCHAEMIC ATTACKS (TIA)

One phenomenon that has received increasing attention is the occurrence of TIA in a fair proportion of cases. These are episodes of focal, reversible, neurological deficit of sudden onset and of less than 24 hours duration. They show a tendency to recurrence. They are due to microemboli, and are a warning sign of stroke.

HOST FACTORS

(i) Age : Stroke can occur at any age. Usually incidence rates rise steeply with age. Globally about 47 per cent of all stroke deaths occur in persons over 70 years. In India, about one-fifth of all strokes occur below the age of 40 (called “strokes in the young”). This is attributed to our “young population”, and shorter life expectancy.

(ii) Sex : The incidence rates are higher in males than females at all ages.

(iii) Personal history : The WHO Study showed that nearly three-quarters of all registered stroke patients had associated diseases, mostly in the cardiovascular system or of diabetes. This supports the view that in most cases stroke is merely an incident in the slowly progressive course of a generalized vascular disease.

Stroke control programme

The aim of a stroke control programme is to apply at community level effective measures for the prevention of stroke. The first priority goes to control of arterial hypertension which is a major cause of stroke. As transient ischaemic attacks (TIA) may be one of the earliest manifestations of stroke, their early detection and treatment is important for the prevention of stroke (2). Control of diabetes, elimination of smoking, and prevention and management of other risk factors at the population level are new approaches. Treatment for acute stroke is largely the control of complications. Facilities for the long-term follow-up of patients are essential. The education and training of health personnel and of the public form an integral part of the programme. For any such programme, reliable knowledge of the extent of the problem in the community concerned is essential (2).

In summary, control of stroke that was once considered an inevitable accompaniment to ageing is now being approached through primary prevention. It has given the hope that stroke can be tackled by community health action.

RHEUMATIC HEART DISEASE

Rheumatic fever (RF) and rheumatic heart disease (RHD) cannot be separated from an epidemiological point of view (1). Rheumatic fever is a febrile disease affecting connective tissues particularly in the heart and joints initiated by infection of the throat by group A beta haemolytic streptococci. Although RF is not a communicable disease, it results from a communicable disease (streptococcal pharyngitis). Rheumatic fever often leads to RHD which is a crippling disease. The consequences of RHD include: continuing damage to the heart; increasing disabilities; repeated hospitalization, and premature death usually by the age of 35 years or even earlier. RHD is one of the most readily preventable chronic disease.

Problem

WORLD

The incidence of rheumatic fever and rheumatic heart disease has not decreased in developing countries. Retrospective studies reveal developing countries to have the highest figures for cardiac involvement and recurrence rates of rheumatic fever. Worldwide, there are over 15 million cases of RHD with 282,000 new cases. During 2008, 220,000 deaths from this disease occurred which is about 0.4 per cent of total deaths (2).

RHD is a major cause of morbidity and a major cause of mitral insufficiency and stenosis in the world. Variables that correlate with the severity of valve disease include the number of previous attacks of RF, the length of time between the onset of disease and start of therapy, and sex (the disease is more severe in females than in males). Insufficiency from acute rheumatic valve disease resolves in 60–80 per cent of patients who adhere to antibiotic prophylaxis (3).

In a number of affluent countries (North America, Western Europe and in Japan) the incidence of RF and the prevalence of and mortality from RHD have fallen during the last two decades, where the disease is now generally uncommon. Some of this decline occurred before modern treatment methods became available, indicating that the fall in prevalence and incidence was associated with social and economic changes (4).

As a result of the above decline, there has been a tendency to minimize the public health importance of RF – the assumption being that the disease may subside or even vanish spontaneously as living standards rise. However, even in the most affluent countries, there remain pockets of poverty where socio-economic conditions continue to favour the persistence of RF (5).

INDIA

In India, RHD is prevalent in the range of 5–7 per thousand in 5–15 years age group and there are about 1 million RHD cases in India. RHD constitutes 20–30% of hospital admissions due to CVD in India (6). Streptococcal infections are very common especially in children living in under-privileged conditions, and RF is reported to occur in 1–3 per cent of those infections (7).

Jai Vigyan Mission Mode project on Community Control of RF/RHD in India is being carried out with four main components, viz. to study the epidemiology of streptococcal sore throats, establish registries for RF and RHD, vaccine development for streptococcal infection and conducting advanced studies on pathological aspects of RF and RHD (7).

Epidemiological factors

1. AGENT FACTORS

(a) AGENT : The onset of RF is usually preceded by a streptococcal sore throat. Of the streptococci, it is the group A streptococcus that has been incriminated as the causative agent. It has been suggested that not all strains of group A streptococci lead to RF; it is believed that there might be some strains with “rheumatogenic potential”. The serotype that has attracted special emphasis is M type 5 which is frequently associated with RF (8). All group A streptococci are sensitive to penicillin. Unfortunately, the group consists of a great number of immunologically different types with little cross immunity, defying all attempts to produce an effective vaccine. Recently the virus (coxsackie B-4) has been suggested as a causative factor and streptococcus acting as a conditioning agent. There are many gaps in our knowledge about the causative agent and underlying pathogenic mechanisms. (b) CARRIERS : Carriers of group A streptococcus are frequent, e.g., convalescent, transient and chronic carriers. In view of the high carrier rate, their eradication is not even theoretically possible (9).

2. HOST AND ENVIRONMENTAL FACTORS

(a) AGE : RF is typically a disease of childhood and adolescence (5–15 years) although it also occurred in adults (20 per cent cases). Mention has already been made about the high incidence of “juvenile mitral stenosis” in India (9, 10). The initial attack of RF occurs at a young age, progresses to valvular lesions faster and is associated with pulmonary arterial hypertension. The cause of the “juvenile” disease in India is not known. (b) SEX : The disease affects both sexes equally but prognosis is worse for females than for males. (c) IMMUNITY : An immunological basis for RF and RHD has been proposed. The most prevalent concept is the toxic-immunological hypothesis. According to this theory, group A streptococcal products have certain toxic products, and components of the streptococcus and of host tissues have an antigenic cross-relationship, leading to immunological processes that result in an attack of RF (11). (d) SOCIO-ECONOMIC STATUS : RF is a social disease linked to poverty, overcrowding, poor housing conditions, inadequate health services, inadequate expertise of health-care providers and a low level of awareness of the disease in the community. It declines sharply when the standard of living is improved, but even in the most affluent countries, there are areas where the disease still exists. (e) HIGH-RISK GROUPS : The school-age children between 5 and 15 years; slum dwellers; and those living in a closed community (e.g., barracks).

Table 1 summarizes the effects of environmental factors on RF and RHD

Clinical features

(a) FEVER : Fever is present at the onset of acute illness and may be accompanied by profuse sweating. It may last for about 12 weeks or longer and has a tendency to recur. (b) POLYARTHRITIS: This occurs in 90 per cent of cases. Large joints like ankles, knees, elbows and wrists are
attack of RF. All layers of the heart—pericardium, myocardium, and the heart valves—are involved. The involvement of heart is manifested by tachycardia, cardiac enlargement, pericarditis and heart failure. The most common ECG finding is the first degree AV block. (d) NODULES: Nodules below the skin tend to appear 4 weeks after the onset of RF. They are small, painless and non-tender. They last for a variable period of time and then disappear leaving no residual damage. (e) BRAIN INVOLVEMENT: This manifests as abnormal jerky purposeless movements of the arms, legs and the body. It gradually disappears leaving no residual damage. (f) SKIN: Various types of skin rash are known to occur. It is thus obvious that except carditis all other manifestations of RF do not cause permanent damage.

Diagnosis

The 2002–2003 WHO criteria for the diagnosis of RF and RHD are based on revised Jones criteria (Table 2) and facilitate the diagnosis of:

- a. primary episode of RF
- b. recurrent attacks of RF in patients without RHD
- c. recurrent attacks of RF in patients with RHD
- d. rheumatic chorea
- e. insidious onset rheumatic carditis
- f. chronic RHD.

For the diagnosis of a primary episode of RF, it is recommended that the major and minor clinical manifestations of RF, the laboratory manifestations, and evidence of a preceding streptococcal infection should all continue according to the 1988 WHO recommendations. In the context of a preceding streptococcal infection, two major manifestations, or a combination of one major and two minor manifestations, provide reasonable evidence for a diagnosis of RF. WHO has continued to maintain that a diagnosis of a recurrence of RF in a patient with established RHD should be permitted on the basis of minor manifestations plus evidence of a recent streptococcal infection.

Prevention

Two preventive approaches are possible:

a. PRIMARY PREVENTION

The aim of primary prevention is to prevent the first attack of RF, by identifying all patients with streptococcal throat infection and treating them with penicillin. While this approach is theoretically simple, in practice, it is difficult to achieve and may not be feasible in many developing countries (4). In order to prevent a single case of RHD, several thousand cases of streptococcal throat infection must be identified and treated. Many infections are inapparent or if apparent are not brought to the attention of the health services; even if they are reported, quick and reliable laboratory services are needed to confirm the diagnosis.

A viable approach is to concentrate on “high-risk” groups such as school-age children. They should be kept under surveillance for streptococcal pharyngitis. Ideally a sore throat should be swabbed and cultured. If streptococci are present, the child should be put on penicillin. Since facilities for throat swab culture are not easily available, it is justified to treat a sore throat with penicillin even without having the culture. For this purpose, a single intramuscular injection of 1.2 million units of benzathine benzyl penicillin for adults and 600,000 units for children is adequate, or oral penicillin (Penicillin V or Penicillin G) should be given for 10 days. This is the least expensive method of giving penicillin for eradication of streptococci from the throat. For patients with allergy to penicillin, erythromycin is the drug of choice. The MCH and school health services should be utilized for this purpose.

In short, the impossible logistics of primary prevention coupled with enormous financial constraints force us to concentrate on secondary prevention (10).

b. SECONDARY PREVENTION

Secondary prevention (i.e., the prevention of recurrences of RF) is a more practicable approach, especially in...

<td>Chronic valve lesions of RHD (patients presenting for the first time with pure mitral stenosis or mixed mitral valve disease and/or aortic valve disease).</td>
<td></td>
</tr>
</tbody>
</table>

a Patients may present with polyarthritis (or with only polyarthritis or monoarthritis) and with several [3 or more] other minor manifestations, together with evidence of recent group A streptococcal infection. Some of these cases may later turn out to be rheumatic fever. It is prudent to consider them as cases of "probable rheumatic fever" (once other diagnoses are excluded) and advise regular secondary prophylaxis. Such patients require close follow-up and regular examination of the heart. This cautious approach is particularly suitable for patients in vulnerable age groups in high incidence settings.

b Infective endocarditis should be excluded.
c Some patients with recurrent attacks may not fulfil these criteria.
d Congenital heart disease should be excluded.

Source: (12)

developing countries. It consists in identifying those who have had RF and giving them one intramuscular injection of benzathine benzyl penicillin (1.2 million units in adults and 600,000 units in children) at intervals of 3 weeks (12). This must be continued for at least 5 years or until the child reaches 18 years whichever is later. For patients with carditis (mild mitral regurgitation or healed carditis) the treatment should continue for 10 years after the last attack, or at least until 25 years of age, which ever is longer. More severe valvular disease or post-valve surgery cases need life-long treatment (12). This prevents streptococcal sore throat and therefore recurrence of RF and RHD.

However, the crucial problem is one of patient compliance as penicillin prophylaxis is a long-term affair. Studies have shown that secondary prevention is feasible, inexpensive and cost-effective, when implemented through primary health care systems (13).

c. NON-MEDICAL MEASURES

Non-medical measures for the prevention/control of RF are related to improving living conditions, and breaking the poverty–disease–poverty cycle. Improvements in socioeconomic conditions (particularly better housing) will in the long term reduce the incidence of RF.

Objective evaluation of available data indicates that penicillin alone will not lead to effective control. Predictions suggest that many of the countries which suffer severe economic constraints will not be likely to be able to raise their standards of living in the foreseeable future to significantly alter the incidence of this disease (9).

d. EVALUATION

In the evaluation of the programme, the prevalence of RHD in school children from periodic surveys of random samples is probably the best indicator. It is suggested that surveys should be carried out on samples of schools (not individuals) in the 6–14 years age group at 5–year intervals. The recommended sample size is 20,000 to 30,000 children depending upon the expected prevalence (13).

CANCER

Cancer may be regarded as a group of diseases characterized by an (i) abnormal growth of cells (ii) ability to invade adjacent tissues and even distant organs, and (iii) the eventual death of the affected patient if the tumour has progressed beyond that stage when it can be successfully removed. Cancer can occur at any site or tissue of the body and may involve any type of cells.

The major categories of cancer are: (a) Carcinomas, which arise from epithelial cells lining the internal surfaces of the various organs (e.g. mouth, oesophagus, intestines,
NON-COMMUNICABLE DISEASES

uterus) and from the skin epithelium; (b) Sarcomas, which arise from mesodermal cells constituting the various connective tissues (e.g. fibrous tissue, fat and bone); and (c) Lymphomas, myeloma and leukaemias arising from the cells of bone marrow and immune systems.

The term "primary tumour" is used to denote cancer in the organ of origin, while "secondary tumour" denotes cancer that has spread to regional lymph nodes and distant organs. When cancer cells multiply and reach a critical size, the cancer is clinically evident as a lump or ulcer localized to the organ of origin in early stages. As the disease advances, symptoms and signs of invasion and distant metastases become clinically evident (1).

Problem statement

WORLD

In 2018, the global burden of cancer rose to an estimated 18.078 million new cases with 9.55 million deaths. The most common cancer diagnosed were cancer lung 2.09 million (11.6%), followed by cancer breast 2.08 million (11.6%), colorectal cancer 1.849 million (10.2%), cancer prostate 1.276 million (7.1%) and stomach cancer 1.033 million (5.7%). The most common cause of cancer deaths were cancer lung 1.76 million (18.4%), colorectal cancer 1.088 million (9.2%), cancer stomach 0.782 million (8.2%), cancer liver 0.761 (8.2%) and cancer breast 0.626 million (6.6%).

Source: (3)
As a consequence of growing and ageing populations, developing countries are disproportionately affected by the increasing numbers of cancers. More than 60 per cent of the world's total cases occur in Africa, Asia, and Central and South America, and these regions account for about 70 per cent of the world's cancer deaths. Situation is made worse by the lack of early detection and access to treatment (4).

The “Westernization” trends: As low human-development index (HDI) countries become more developed through rapid societal and economic changes, they are likely to become “westernized”. As such, the pattern of cancer incidence is likely to follow that seen in high HDI settings, with likely decline in cancer incidence rate of cervix uteri and stomach, and increasing incidence rates of breast, prostate and colorectal cancers. This westernization effect is a result of reduction in infection-related cancers and increase in cancers associated with reproductive, dietary and hormonal risk factors (5).

For any disease, the relationship of incidence to mortality is an indication of prognosis. Similar incidence and mortality rates being indicative of an essentially fatal condition. Thus, lung cancer accounts for most deaths from cancer in the world (1.6 million) annually, since it is most invariably associated with poor prognosis. On the other hand, appropriate intervention is often effective in avoiding fatal outcome following diagnosis of breast cancer. Hence this particular cancer, which rank second in terms of incidence, is not among the top three causes of death from cancer, which are respectively cancers of the lung, stomach, and liver.

The most conspicuous feature of the distribution of cancers between the sexes is the male predominance of lung cancer. Prostate, colorectal, stomach and liver cancer are also much more common in males. Cancer of breast, colorectum, lung, cervix, uteri and stomach are common in females (3). For the most part, differences in distribution between the sexes are attributable to differences in exposure to causative agents rather than to variation in the susceptibility. For other tumour types, including cancers of pancreas and colorectum, there is little difference in the sex distribution. Generally speaking, the relationship of incidence to mortality is not affected by sex. Thus for example, the prognosis following diagnosis of liver or pancreatic cancer is dismal for both males and females. Many other tumour types are more responsive to therapy, so that cancers of breast, prostate and uterine cervix are the cause of death in only a minority of patients diagnosed (6).

The burden of cancer is distributed unequally between developed and developing countries, with particular cancer types exhibiting different patterns of distribution.

INDIA

In India, the National Cancer Registry Programme of the ICMR provides data on incidence, mortality and distribution of cancer from 25 population-based registries and 5 hospital based registries.

Prevalence of cancer in India is estimated to be 3.9 million and reported incidence to be about 1.1 million. The age standardized incidence is estimated to be about 150-200 per 100,000 population (7). The DALYs lost due to top 10 types of cancer in men and women are as shown in Fig. 2.

CANCER accounted for 9 per cent of all deaths in 2016, double that of 1990. In absolute numbers, the situation is alarming. Cancer liver was the fastest growing cancer. The age-standardized data for 1990 and 2016 are compared in Fig. 3.

The five most frequent cancers in men were cancer lung, lip and oral cavity, stomach, colorectum and other pharynx, and in women, cancer breast, cervix uteri, colorectum, ovary, lip and oral cavity. Cancer in males were mostly tobacco related. In women, cervical cancer is closely associated with poor genital hygiene, early consummation of marriage, multiple pregnancies, and contact with multiple sexual partners. It is also reported that breast cancer is proportionately on the increase in a few metropolitan areas of India. This appears to be related to late marriage, birth of the first child at a late age, fewer children, and shorter periods of breast-feeding, which are increasingly common practice among the educated urban women (9).
Facilities for screening and proper management of cancer patients are grossly limited in India. More than two-thirds of cancer patients are already in an advanced and incurable stage at the time of diagnosis. Appropriate strategies are being developed, including creating public awareness about cancer, tobacco control and application of self or assisted screening technique for oral, cervical, and breast cancers.

Time trends

Few decades ago, cancer was the sixth leading cause of death in industrialized countries; today, it is the second leading cause of death. There are a number of reasons for this increase, the three main ones being a longer life expectancy, more accurate diagnosis and the rise in cigarette smoking, especially among males. The overall rates do not reflect the different trends according to the type of cancer. For example, there has been a large increase in lung cancer incidence and the stomach cancer has shown a declining trend in most developed countries for reasons not understood.

Cancer patterns

There are wide variations in the distribution of cancer throughout the world. That cancer of the stomach is very common in Japan, and has a low incidence in United States. The cervical cancer is high in Columbia and has a low incidence in Japan. In the South-East Asia Region of WHO, the great majority are cancers of the oral cavity and uterine cervix. These and other international variations in the pattern of cancer are attributed to multiple factors such as environmental factors, food habits, lifestyle, genetic factors or even inadequacy in detection and reporting of cases.

Hospital data clearly indicates that the two organ sites most commonly involved are: (i) the uterine cervix in women, and (ii) the oropharynx in both sexes. These two sites represent approximately 50 per cent of all cancer cases. Both these cancers are predominantly environment related and have a strong socio-cultural relationship. It is also important to note that these two kinds of cancer are easily accessible for physical examination and amenable to early diagnosis by knowledge already available, i.e., good clinical examination and exfoliative cytology. The cure rate for these neoplasia is also very high if they are treated surgically at stages I and II. But unfortunately, in most cases, the patients present themselves to a medical facility when the disease is far advanced and is not amenable to treatment. This is the crux of the problem.

Causes of cancer

As with other chronic diseases, cancer has a multifactorial aetiology

1. ENVIRONMENTAL FACTORS

Environmental factors are generally held responsible for 60 to 90 per cent of all human cancers. The major environmental factors identified so far include:

(a) TOBACCO: Tobacco in various forms of its usage (e.g., smoking, chewing) is the major environmental cause of cancers of the lung, larynx, mouth, pharynx, oesophagus, bladder, pancreas and probably kidney. It has been estimated that, in the world as a whole, cigarette smoking is now responsible for more than one million premature deaths each year (10).

(b) ALCOHOL: Excessive intake of alcoholic beverages is associated with oesophageal and liver cancer. Some recent studies have suggested that beer consumption may be associated with rectal cancer (11). It is estimated that alcohol contributed to about 3 per cent of all cancer deaths (12).

(c) DIETARY FACTORS: Dietary factors are also related to cancer. Smoked fish is related to stomach cancer, dietary fibre to intestinal cancer, beef consumption to bowel cancer and a high fat diet to breast cancer. A variety of other dietary factors such as food additives and contaminants have fallen under suspicion as causative agents. (Refer to chapter 10 for further details.)

(d) OCCUPATIONAL EXPOSURES: These include exposure to benzene, arsenic, cadmium, chromium, vinyl chloride, asbestos, polycyclic hydrocarbons, etc. Many others remain to be identified. The risk of occupational exposure is considerably increased if the individuals also smoke cigarettes. Occupational exposures are usually reported to account for 1 to 5 per cent of all human cancers (13).

(e) VIRUSES: An intensive search for a viral origin of human cancers revealed that hepatitis B and C virus is causally related to hepatocellular carcinoma. The relative risk of Kaposi's sarcoma occurring in patients with HIV infection is so high that it was the first manifestation of the AIDS epidemic to be recognized. Non-Hodgkin's lymphoma, a cancer of the lymph nodes and spleen is a late complication of AIDS. The Epstein-Barr virus (EBV) is associated with 2 human malignancies, viz. Burkitt's lymphoma and nasopharyngeal carcinoma. Cytomegalovirus (CMV) is a suspected oncogenic agent and classical Kaposi's sarcoma is associated with a higher prevalence of antibodies to CMV. Human papilloma virus (HPV) is a chief suspect in cancer cervix. Hodgkin's disease is also believed to be of viral origin. The human T-cell leukaemia virus is associated with adult T-cell leukaemia/lymphoma in the United States and southern parts of Japan (6, 14).

(f) PARASITES: Parasitic infections may also increase the risk of cancer, as for example, schistosomiasis in Middle East producing carcinoma of the bladder. (g) CUSTOMS, HABITS AND LIFESTYLES: To the above causes must be added customs, habits and lifestyles of people which may be associated with an increased risk for certain cancers. The familiar examples are the demonstrated association between smoking and lung cancer, tobacco and betel chewing and oral cancer, etc (15).

(h) OTHERS: There are numerous other environmental factors such as sunlight, radiation, air and water pollution, medications (e.g., oestrogen) and pesticides which are related to cancer.

2. GENETIC FACTORS

Genetic influences have long been suspected. For example, retinoblastoma occurs in children of the same parent. Mongols are more likely to develop cancer (leukaemia) than normal children. However, genetic factors are less conspicuous and more difficult to identify. There is probably a complex interrelationship between hereditary susceptibility and environmental carcinogenic stimuli in the causation of a number of cancers.

Cancer control

Cancer control consists of a series of measures based on present medical knowledge in the fields of prevention, detection, diagnosis, treatment, after care and rehabilitation, aimed at reducing significantly the number of new cases, increasing the number of cures and reducing the invalidism due to cancer.

The basic approach to the control of cancer is through primary and secondary prevention. It is estimated that at least one-third of all cancers are preventable (16).
1. PRIMARY PREVENTION

Cancer prevention until recently was mainly concerned with the early diagnosis of the disease (secondary prevention), preferably at a precancerous stage. Advancing knowledge has increased our understanding of causative factors of some cancers and it is now possible to control these factors in the general population as well as in particular occupational groups. They include the following:

(a) CONTROL OF TOBACCO AND ALCOHOL CONSUMPTION: Primary prevention offers the greatest hope for reducing the number of tobacco-induced and alcohol related cancer deaths. It has been estimated that control of tobacco smoking alone would reduce the total burden of cancer by over a million cancers each year (17). (b) PERSONAL HYGIENE: Improvements in personal hygiene may lead to declines in the incidence of certain types of cancer, e.g., cancer cervix. (c) RADIATION: Special efforts should be made to reduce the amount of radiation (including medical radiation) received by each individual to a minimum without reducing the benefits. (d) OCCUPATIONAL EXPOSURES: The occupational aspects of cancer are frequently neglected. Measures to protect workers from exposure to industrial carcinogens should be enforced in industries. (e) IMMUNIZATION: In the case of primary liver cancer, immunization against hepatitis B virus and for prevention of cancer cervix immunization against HPV presents an exciting prospect. (f) FOODS, DRUGS AND COSMETICS: These should be tested for carcinogens. (g) AIR POLLUTION: Control of air pollution is another preventive measure. (h) TREATMENT OF PRECANCEROUS LESIONS: Early detection and prompt treatment of precancerous lesions such as cervical tears, intestinal polyposis, warts, chronic gastritis, chronic cervicitis, and adenoma is one of the cornerstones of cancer prevention.

(i) LEGISLATION: Legislation has also a role in primary prevention. For example, legislation to control known environmental carcinogens (e.g., tobacco, alcohol, air pollution). (j) CANCER EDUCATION: An important area of primary prevention is cancer education. It should be directed at "high-risk" groups. The aim of cancer education is to motivate people to seek early diagnosis and early treatment. Cancer organizations in many countries remind the public of the early warning signs ("danger signals") of cancer. These are:

- a lump or hard area in the breast
- a change in a wart or mole
- a persistent change in digestive and bowel habits
- a persistent cough or hoarseness
- excessive loss of blood at the monthly period or loss of blood outside the usual dates
- blood loss from any natural orifice
- a swelling or sore that does not get better
- unexplained loss of weight.

There is no doubt that the possibilities for primary prevention are many. Since primary prevention is directed at large population groups (e.g., high risk groups, school children, occupational groups, youth clubs), the cost can be high and programmes difficult to conduct. Primary prevention, although a hopeful approach, is still in its early stages. Major risk factors have been identified for a small number of cancers only and far more research is needed in that direction.

2. SECONDARY PREVENTION

Secondary prevention comprises the following measures:

i) CANCER REGISTRATION

Cancer registration is a sine qua non for any cancer control programme. It provides a base for assessing the magnitude of the problem and for planning the necessary services. Cancer registries are basically of two types: hospital-based and population based. (a) HOSPITAL-BASED REGISTRIES: The hospital-based registry includes all patients treated by a particular institution, whether in-patients or out-patients. Registries should collect the uniform minimum set of data recommended in the "WHO Handbook for Standardized Cancer Registries" (18). If there is a long-term follow-up of patients, hospital-based registries can be of considerable value in the evaluation of diagnostic and treatment programmes. Since hospital population will always be a selected population, the use of these registries for epidemiological purposes is thus limited. (b) POPULATION-BASED REGISTRIES: A right step is to set up a "hospital-based cancer registry" and extend the same to a "population-based cancer registry". The aim is to cover the complete cancer situation in a given geographic area. The optimum size of base population for a population based cancer registry is in the range of 2-7 million (19). The data from such registries alone can provide the incidence rate of cancer and serve as a useful tool for initiating epidemiological enquiries into causes of cancer, surveillance of time trends, and planning and evaluation of operational activities in all main areas of cancer control.

ii) EARLY DETECTION OF CASES

Cancer screening is the main weapon for early detection of cancer at a pre-invasive (in situ) or pre-malignant stage. Effective screening programmes have been developed for cervical cancer, breast cancer and oral cancer. Like primary prevention, early diagnosis has to be conducted on a large scale; however, it may be possible to increase the efficiency of screening programmes by focussing on high-risk groups. Clearly, there is no point in detecting cancer at an early stage unless facilities for treatment and after-care are available. Early detection programmes will require mobilization of all available resources and development of a cancer infrastructure starting at the level of primary health care, ending with complex cancer centres or institutions at the state or national levels.

iii) TREATMENT

Treatment facilities should be available to all cancer patients. Certain forms of cancer are amenable to surgical removal, while some others respond favourably to radiation or chemotherapy or both. Since most of the known methods of treatment have complementary effect on the ultimate outcome of the patient, multi-modality approach to cancer control has become a standard practice in cancer centres all over the world. In the developed countries today, cancer treatment is geared to high technology. For those who are beyond the curable stage, the goal must be to provide pain relief. A largely neglected problem in cancer care is the management of pain. The WHO has developed guidelines on relief of cancer pain (20). "Freedom from cancer pain" is now considered a right of cancer patients.

CANCER SCREENING

In the light of present knowledge, early detection and prompt treatment of early cancer and precancerous
conditions provide the best possible protection against cancer for the individual and the community. Now a good deal of attention is being paid to screening for early detection of cancer. This approach, that is, cancer screening may be defined as the "search for unrecognized malignancy by means of rapidly applied tests".

Cancer screening is possible because: (a) in many instances, malignant disease is preceded by a period of months or years by a premalignant lesion, removal of which prevents subsequent development of cancer; (b) most cancers begin as localized lesions and if found at this stage a high rate of cure is obtainable; and (c) as much as 75 per cent of all cancers occur in body sites that are accessible.

METHODS OF CANCER SCREENING

(a) Mass screening by comprehensive cancer detection examination: A rapid clinical examination, and examination of one or more body sites by the physician is one of the important approaches for screening for cancer. (b) Mass screening at single sites: This comprises examination of single sites such as uterine cervix, breast or lung. (c) Selective screening: This refers to examination of those people thought to be at special risk, for example, parous women of lower socio-economic strata upwards of 35 years of age for detection of cancer cervix, chronic smokers for lung cancer, etc.

1. Screening for cancer cervix

Screening for cervical cancer has become an accepted clinical practice. The prolonged early phase of cancer in situ can be detected by the Pap smear. Current policy suggests that all women should have a Pap test (cervical smear) at the beginning of sexual activity, and then every 3 years thereafter (21). A periodic pelvic examination is also recommended. Organized population based screening programmes have reduced the incidence and mortality from cervical cancer in many developed countries.

However, screening for cancer cervix using Pap smear requires excessive resources in terms of laboratories, equipments and trained personnel. This has led to search for an alternative screening method that can be more cost-effective. Visual inspection based screening tests such as visual inspection with 5 per cent acetic acid (VIA), VIA with magnification (VIAM), and visual inspection post application of Lugol's iodine (VILI) are some of the alternative screening tests, which have been studied for their effectiveness in India. Sensitivity of VIA tends to be similar to cytology based screening. It is easy to carry out and easy to train appropriate health workers (22).

The present strategy is to screen women using visual inspection after application of freshly prepared 5 per cent acetic acid solution (5 ml of glacial acetic acid mixed with 95 ml distilled water). Detection of well-defined opaque acetowhite lesions close to the squamo-columnar junction, well defined circum-orificial acetowhite lesion or dense acetowhitening of ulceroproiferative growth on the cervix constitute a positive VIA or VIAM. The test is followed by a single visit approach for further investigation and management at district hospital. The management at district hospital is planned in such a way that the treatment based on colposcopy is offered in the same visit. Pap smear and biopsy are the investigations that are done to ensure that there are cytological and histopathological back-up for the interventions (22).

Intensive information, education and communication activities are required to sensitize the community about the significance of the disease and its early detection through screening.

2. Screening for breast cancer

There is evidence that screening for breast cancer has a favourable effect on mortality from breast cancer. The basic techniques for early detection of breast cancer are: (a) breast self-examination (BSE) by the patient (b) palpation by a physician (c) thermography, and (d) mammography.

All women should be encouraged to perform breast self-examination. Breast cancers are more frequently found by women themselves than by a physician during a routine examination. Although the effectiveness of BSE has not been adequately quantified, it is a useful adjuvant to early case detection. In many countries, BSE will probably be the only feasible approach to wide population coverage for a long time to come. Palpation is unreliable for large fatty breasts. Thermography has the advantage that the patient is not exposed to radiation. Unfortunately, it is not a sensitive tool. Mammography is most sensitive and specific in detecting small tumours that are sometimes missed on palpation. The use of mammography has three potential drawbacks: (i) exposure to radiation. This may amount to a dose of 500 milliroentgen compared to a 30-40 milliroentgen dose received in chest X-ray. Therefore, there has been concern about exposure to radiation from repeated mammographies and the risk of breast cancer developing as a result (ii) mammography requires technical equipment of a high standard and radiologists with very considerable experience — these two factors limit its more widespread use for mass screening purposes, and (iii) biopsy from a suspicious lesion may end up in a false-positive in as many as 5-10 cases for each case of cancer detected.

Although recent evidence points to the superiority of mammography over clinical examination in terms of sensitivity and specificity (23), medical opinion is against routine mammography on the very young. Women under 35 years of age should not have X-rays unless they are symptomatic or a family history of early onset of breast cancer (24).

3. Screening for lung cancer

At present there are only two techniques for screening for lung cancer, viz. chest radiograph and sputum cytology. Mass radiography has been suggested for early diagnosis at six monthly intervals, but the evidence in support of this is not convincing. So it is not recommended. It is doubtful whether the disease satisfies the criteria of suitability for screening (see chapter 4).

EPIDEMIOLOGY OF SELECTED CANCERS

1. Oral cancer

Oral cancer is one of the ten most common cancers in the world. Its high frequency in Central and South East Asian countries (e.g., India, Bangladesh, Sri Lanka, Thailand, Indonesia, Pakistan) has been well documented. It is estimated that during the year 2018 (September), about 246,420 men and 108,444 women were having oral cancer. About 119,693 men and 57,691 women died of oral cancer worldwide with a mortality rate of 2.2 per 100,000 population (2).

Oral cancer is a major problem in India. It is estimated that in 2016 it caused 4.5 deaths per 100,000 population.
(total 59,000 deaths), 41,200 deaths in men and 17,800 deaths in women (25). The age standardized incidence rate was 5.3 per 100,000 population (25).

EPIDEMIOLOGICAL FEATURES

(a) Tobacco: Approximately 90 per cent of oral cancers in South East Asia are linked to tobacco chewing and tobacco smoking. During 1966–1977, a large epidemiological survey was carried out in different parts of the country. In this 10-year follow-up study of 30,000 individuals in the three districts of Ernakulam (Kerala), Srikakulam (Andhra), and Bhavnagar (Gujarat), the results indicated that (i) oral cancer and precancerous lesions occurred almost solely among those who smoked or chewed tobacco, and (ii) oral cancer was almost always preceded by some type of precancerous lesion (26, 27). The case about tobacco is further strengthened by the findings that the cancer almost always occurred on the side of the mouth where the tobacco quid was kept (28), and the risk was 36 times higher than for non-chewers if the quid was kept in the mouth during sleep (29).

(b) Alcohol: Data indicates that oral cancer can also be caused by high concentrations of alcohol, and that alcohol appears to have a synergistic effect in tobacco users (28).

c. Pre-cancerous stage: The natural history of oral cancer shows that often a precancerous stage precedes the development of cancer. The pre-cancerous lesions (leukoplakia, erythroplakia) can be detected for up to 15 years prior to their change to an invasive carcinoma (28). Intervention at this stage may result in regression of the lesion.

d. High-risk groups: These include tobacco chewers and smokers, bidi smokers, people using tobacco in other forms such as betel quid; people who sleep with the tobacco quid in the mouth (30).

e. Cultural patterns: In studying the tobacco habits in developing countries, indigenous forms of smoking, as well as chewing, which are characteristic of certain regions have to be taken into account (10). Tobacco is smoked in the form of manufactured cigarettes. The indigenous forms of smoking are: chiti, chutta (cigar), chilum, hookah (hubble-bubble). Tobacco in powdered form is inhaled as snuff.

The most common form of tobacco chewing in India is the betel quid which usually consists of the betel leaf, arecanut, lime and tobacco. It is common for the poorer people to rub with the thumb flakes of sun-dried tobacco and slaked lime in the palm of their left hand until the desired mixture is obtained. The mixture (khaini) is then put into the mouth in small amounts and at frequent intervals during the day and slowly sucked and swallowed after dilution with saliva.

Cancer of the oral cavity is also very prevalent in Central Asian districts of USSR, where people chew "nass" or "nasswar" – a mixture of tobacco, ashes, lime and cottonseed oil.

Another type of cancer common in the eastern coastal regions of Andhra Pradesh state in India is the epidermoid carcinoma of the hard palate. It is associated with the habit of reverse smoking of cigar (chutta), i.e., smoking with the burning end inside the mouth (31).

PREVENTION

a. PRIMARY PREVENTION

Oral cancer is amenable to primary prevention. If the tobacco habits are eliminated from the community, a great deal of reduction in the incidence of oral cancer can be achieved. This requires intensive public education and motivation for changing lifestyles supported by legislative measures like banning or restricting the sale of tobacco.

b. SECONDARY PREVENTION

Oral cancers are easily accessible for inspection allowing early detection. If detected early, possibly at the precancerous stage, they can be treated or cured. The precancerous lesions can be detected for up to 15 years prior to their change to an invasive carcinoma. Leukoplakia can be cured by cessation of tobacco use. The main treatment modalities that offer hope are surgery and radiotherapy (32). In developing countries over 50 per cent of oral cancers are detected only after they have reached an advanced stage (16).

The primary health care workers (village health guides, and multi-purpose workers) are in a strategic position to detect oral cancers at an early stage during home visits. They can prove to be a vital link and a key instrument in the control of oral cancer in developing countries (33).

2. Cancer of the cervix

Cervical cancer is the fourth most frequent cancer in women with an estimated 570,000 new cases in 2018 representing 6.6 per cent of all female cancers (34). During the year (up to Sept, 2018) about 311,365 women died of cervical cancer, which comes to 3.2 per cent of all deaths due to cancer in women. Approximately 90 per cent of deaths from cervical cancer occurred in low and middle income countries. Wide variations in incidence and mortality from the disease exist between countries. Cases and deaths have declined markedly in the last 40 years in most industrialized countries, partly owing to a reduction in risk factors, but mainly as a result of extensive screening programmes. More limited improvements have been observed in developing countries, where persistently high rates tend to be the rule (1).

In India, cancer cervix constitutes 14 per cent of all cancer incidence among women. The age standardized incidence rate is about 6.5 per 100,000 population. The estimated deaths were 72,700 in 2016 (25).

NATURAL HISTORY

(a) The disease: Cancer cervix seems to follow a progressive course from epithelial dysplasia to carcinoma in situ to invasive carcinoma (Fig. 1). There is good evidence that carcinoma in situ persists for a long time, more than 8 years on an average (21). The proportion of cases progressing to invasive carcinoma from preinvasive stage is not known – it may average 15 to 20 years or longer (35). The duration of the preinvasive stage is also not known. There is evidence that some in situ cases will spontaneously regress without treatment. Once the invasive stage is reached, the disease spreads by direct extension into the lymph nodes and pelvic organs.

(b) Causative agent: There is evidence pointing to Human papilloma virus (HPV) – sexually transmitted – as the cause of cervical cancer (36). This virus was once
supposed to produce only vegetant warts, but now acknowledged as responsible for a much wider clinical and subclinical lesions. The virus is found in more than 95% of the cancers. Current evidence suggests that the virus is a necessary but not sufficient cause of the disease and researchers are now trying to define other co-factors.

RISK FACTORS

(a) AGE: Cancer cervix affects relatively young women with incidence increasing rapidly from the age of 25 to 45, then levelling off, and finally falling again. (b) GENITAL WARTS: Past and/or present occurrence of clinical genital warts has been found to be an important risk factor (36). (c) MARITAL STATUS: Cases are less likely to be single, more likely to be widowed, divorced or separated and having multiple sexual partners. The fact that cancer of the cervix is very common in prostitutes and practically unknown among virgins suggests that the disease could be linked with sexual intercourse. (d) EARLY MARRIAGE: Early marriage, early colitus, early childbirth and repeated childbirth have been associated with increasing risk. (e) ORAL CONTRACEPTIVE PILLS: There is renewed concern about the possible relationship between pill use and the development of invasive cervical cancer (37). A recent WHO study finds an increased risk with increased duration of pill use and with the use of oral contraceptives high in oestrogen (38). (f) SOCIO-ECONOMIC CLASS: Cancer cervix is more common in the lower socio-economic groups reflecting probably poor genital hygiene.

PREVENTION AND CONTROL

(a) PRIMARY PREVENTION: Until the causative factors are more clearly understood, there is no prospect of primary prevention of the disease (35). It may be that with improved personal hygiene and birth control, cancer of the cervix uteri will show the same decline in developing countries as already experienced in most of Europe and North America (39).

(b) SECONDARY PREVENTION: This rests on early detection of cases through screening and treatment by radical surgery and radiotherapy. The 5-year survival rate is virtually 100 per cent for carcinoma in situ, 79 per cent for local invasive disease and 45 per cent for regional invasive disease (21). Cancer cervix is difficult to cure once symptoms develop and is fatal if left untreated. Prognosis is strongly dependent upon the stage of disease at detection and treatment.

3. Breast cancer

Breast cancer is by far the most frequent cancer among women with on estimated 2.1 million new cases diagnosed in 2018 (upto Sept.). It is now the most common cancer both in developed and developing regions. The incidence of breast cancer varies from 911,014 in Asia to 24,561 in Oceania countries. European countries (522,513 cases) are second to Asian countries. The range of mortality is similar, approximately 310,577 deaths in Asian countries and 137,707 in European countries. The 5 years prevalence is 38.2 per cent in Asia and 29.9 per cent in Europe (2). Although breast cancer is the most common cancer, it ranks fifth in terms of mortality rate because of more favourable survival rate in developed countries, but in developing countries it is still most frequent cause of death.

In India, breast cancer was estimated to cause 6.1 deaths per 100,000 population in the year 2016. The survival rate decreased by 2.7 times for breast cancer, in case of detection at stage IV as against stage I. A total of 80,700 women died of cancer breast in 2016 in India (25).

RISK FACTORS

The established risk factors of breast cancer include the following:

(a) AGE: Breast cancer is uncommon below the age of 35, the incidence increasing rapidly between the ages of 35 and 50. A slight bimodal trend in the age distribution has been observed (40) with a dip in incidence at the time of menopause. A secondary rise in frequency often occurs after the age of 65. Women who developed their first breast cancer under the age of 40, had three times the risk of developing a second breast cancer than did those who developed their first cancer after the age of 40 (41). Indeed the aetiologies of pre-menopausal and post-menopausal breast cancer appears to be different (42).

Breast cancer is not only infrequent in Indian women, but also it occurs in them a decade earlier than in Western women — the mean age of occurrence is about 42 in India, as compared to 53 in the white women.

(b) FAMILY HISTORY: The risk is high in those with a positive family history of breast cancer, especially if a mother or sister developed breast cancer when premenopausal.

(c) PARITY: MacMahon, et al (43) in their international case-control study found that the risk of breast cancer is directly related to the age at which women bear the first child. An early first, full-term pregnancy seems to have a protective effect. Those whose first pregnancy is delayed to their late thirties are at a higher risk than multiparous women. Unmarried women tend to have more breast tumours than married single women, and nulliparous women had the same risk.

(d) AGE AT MENARCHE AND MENOPAUSE: Early menarche and late menopause are established risk factors (44). The risk is reduced for those with a surgically induced menopause. Forty or more years of menstruation doubles the risk of breast cancer as compared with 30 years (45).

(e) HORMONAL FACTORS: The association of breast cancer with early menarche and late menopause suggests that ovary appears to play a crucial role in the development of breast cancer. Evidence suggests that both elevated oestrogen as well as progesterone are important factors in increasing breast cancer risk (46). In short, hormones appear to hold the key to the understanding of breast cancer.

(f) PRIOR BREAST BIOPSY: Prior breast biopsy for benign breast disease is associated with an increased risk of breast cancer.

(g) DIET: Current aetiological hypotheses suggest that cancer of the breast is linked with a high fat diet and obesity. It is not known how dietary fat influences breast cancer risk at a cellular level (46).

(h) SOCIO-ECONOMIC STATUS: Breast cancer is common in higher socio-economic groups. This is explained by the risk factor of higher age at first birth.

(i) OTHERS: (i) Radiation: An increased incidence of breast cancer has been observed in women exposed to radiation. (ii) Oral contraceptives: Oral contraceptive appears to have little overall effect on breast cancer, although prolonged use of oral pills before the first pregnancy or before the age of 25 may increase the risk in younger women (47).
PREVENTION

a. PRIMARY PREVENTION

Current knowledge of the aetiology of breast cancer (39) offers little prospect of primary prevention. However, the aim should be towards elimination of risk factors discussed above and promotion of cancer education. The average age at menarche can be increased through a reduction in childhood obesity, and an increase in strenuous physical activity; and the frequency of ovulation (after menarche) decreased by an increase in strenuous physical activity (48). There is also good reason for reducing fat intake in the diet.

b. SECONDARY PREVENTION

Breast screening leads to early diagnosis of breast cancer, which in turn influences treatment and, hopefully, mortality. An important component of secondary prevention is follow-up, i.e., to detect recurrence as early as possible; to detect cancer in the opposite breast at an early stage; and to generate research data that might be useful (42).

No major improvement in survival rates has yet been shown by current treatment modalities. Some cases progress rapidly even if diagnosed at an apparently early stage, others surviving for 20 years even after metastatic spread. However, in general, the removal of the tumour early is more likely to be curative than removal at a later stage (32).

4. Lung cancer

MAGNITUDE OF THE PROBLEM

Lung cancer has been known in industrial workers from the late 19th century. It came into prominence as a public health problem in the Western world in 1930s – at first in men, and later (in 1960s) among women (49), and has followed the increasing adoption of cigarette smoking first by men and later by women. According to WHO reports, between 1960 and 1980, the death rate due to lung cancer increased by 76 per cent in men and by 135 per cent in women (50, 30). In countries where cigarette smoking has only recently begun to be widely adopted, lung cancer deaths still remain low, but it may be expected that they will rise soon. In others, such as Poland, where the use of cigarettes began earlier, the rise is already occurring. The total burden of lung cancer in any country is directly related to the amount and duration of cigarette smoking.

Worldwide, lung cancer remains the leading cause of cancer incidence and mortality, with 2.1 million new lung cancer cases and 1.8 million deaths predicted in 2018, representing close to 1 in 5 (18.4 per cent) cancer deaths. Among males, lung cancer is the leading cause of death in most countries in Eastern Europe, Western Asia, Northern Africa and South East Asia. It caused 1,368,524 new cases and 1,184,947 deaths in men. Among women it caused 725,352 new cases and 576,060 deaths. The 5 years prevalence was highest in Asia (56.6 per cent) followed by Europe 23.3 per cent (3).

In India, the age standardized incidence rate for the year 2016 was: total 8.4 per 100,000 population; for men 12.6 per 100,000 population and women 4.3 per 100,000 population. The Estimated deaths were 89,300, of which 65,800 were men and 23,500 were women. The crude death rate was 6.7 per 100,000 population, of which 9.6 per 100,000 was for men and 3.7 per 100,000 population for women (25).

EPIDEMIOLOGICAL FEATURES

a. AGE AND SEX

About a third of all lung cancer deaths occur below the age of 65. In many industrialized countries, the incidence of lung cancer is at present increasing more in females than in males (51).

b. RISK FACTORS

(i) Smoking: Tobacco smoking was first suggested as a cause of lung cancer in the 1920s. Subsequent studies proved the causal relationship between cigarette smoking and lung cancer. Two studies in India showed that the lung cancer risk for cigarette smokers is 8.6 times the risk for non-smokers (52, 53). The risk is strongly related to the number of cigarettes smoked, the age of starting to smoke and smoking habits, such as inhalation and the number of puffs and the nicotine, the tar content and the length of cigarettes. Those who are highly exposed to “passive smoking” (somebody else’s smoke) are at an increased risk of developing lung cancer. It has been calculated that in countries where smoking has been a widespread habit, it is responsible for 90 per cent of lung cancer deaths (54). The strongest evidence that cigarette smoking is responsible for lung cancer is the incidence reduction that occurs after cessation of smoking. This has been convincingly demonstrated in a 20 year prospective study on male British doctors (55).

The most noxious components of tobacco smoke are tar, carbon monoxide and nicotine. The carcinogenic role of tar is well established. Nicotine and carbon monoxide, particularly, contribute to increased risk of cardiovascular diseases through enhancement of blood coagulation in the vessels, interference with myocardial oxygen delivery, and reduction of the threshold for ventricular fibrillation (10).

A study in India has shown that there is no difference between the tar and nicotine delivery of the filter and non-filter cigarettes smoked in India, so that a filter gives no protection to Indian smokers. The “king-size” filter cigarettes deliver more tar and nicotine than ordinary cigarettes. Bidi smoking appears to carry a higher lung cancer risk than cigarette smoking owing to the higher concentration of carcinogenic hydrocarbons in the smoke (10).

(ii) Other factors: Besides cigarette smoking, there are other factors which are implicated in the aetiology of lung cancer. These include air pollution, radioactivity, and occupational exposure to asbestos, arsenic and its compounds, chromates, particles containing polycyclic aromatic hydrocarbons and certain nickel-bearing dusts. A number of studies have shown an interaction between smoking and asbestos exposure.

PREVENTION

1. PRIMARY PREVENTION

In lung cancer control, primary prevention is of greatest importance. The most promising approach is to control the “smoking epidemic”, because 80 to 90 per cent of all cases of lung cancer in developed countries are due to smoking of cigarettes (52). Methods of controlling the smoking epidemic have been described by the WHO expert committees in their reports (51, 55). Broadly these methods include:

a. Public information and education
b. Legislative and restrictive measures
c. Smoking cessation activities
d. National and International coordination
a. Public information and education

The need of the hour is to create public awareness about the hazards of smoking through mass media. The target population should be the entire population with greater emphasis laid on young people and school children. Nothing less than a national anti-smoking campaign will be needed to change human behaviour or life styles associated with smoking. Curtailment of smoking must be an essential part of national health policy.

b. Legislative and restrictive measures

Legislation and restrictive measures have been suggested in the following areas: control of sales promotion; health warnings on cigarette packets and advertisements; product description showing yield of harmful substances; imposition of upper limits for harmful substances in smoking materials; taxation; sales restrictions; restriction on smoking in public places; restriction on smoking in places of work, etc. (54).

The Government of India have provided legislative support to the anti-smoking campaign. “The Cigarettes (Regulation of production, supply and distribution) Act of 1975” which came into force from 1 April 1976, requires all manufacturers or persons trading in cigarettes to display prominently the statutory warning “Cigarette Smoking is Injurious to Health” on all cartons or packets of cigarettes that are put on sale. Most of the State Governments in India have promulgated laws prohibiting smoking in closed areas, e.g., cinemas, buses, educational institutions, and hospitals. Again in the year 2003, a comprehensive tobacco control legislation titled “The Cigarettes And Other Tobacco Products (Prohibition of Advertisement and Regulation of Trade and Commerce, Production, Supply and Distribution) Act 2003 was passed by the Govt of India. Refer to chapter 7 “National cancer control programme” for the details.

c. Smoking cessation activities

Research continues on different methods of smoking cessation. In all countries well over 90 per cent of those who give up smoking do so of their own volition, i.e., without use of any specific therapy. The basic role of most treatments for smoking cessation would be to relieve the smoker of “abstinence symptoms” (e.g., sleeplessness, craving for smoking, dizziness, constipation, etc). The report of the WHO expert committee (54) on smoking control contains information on specific smoking cessation methods such as smoking cessation clinics, nicotine substitutes, hypnosis, etc.

d. National and international coordination

Since smoking is a worldwide epidemic, it requires coordinated political and non-political approaches at local, national and international levels to contain the smoking epidemic.

2. SECONDARY PREVENTION

This rests on early detection of cases and their treatment. At present, there are only two procedures capable of detecting presymptomatic, early-stage lung cancer. These are the chest X-ray and sputum cytology. But screening for early-stage lung cancer is less attractive, more expensive and appears to have less potential for reducing mortality than primary prevention. Therefore, mass screening for lung cancer is not recommended as a routine public health policy (51).

Efforts to find effective treatment for lung cancer have met with only limited success. For untreated patients, the median survival is 2 to 3 months, compared to 10–14 months for patients receiving combined chemotherapy. In view of these limitations, primary prevention merits greater attention. An important part of treatment is relief of pain so that each dying patient has the right to spend his last days as pain-free as possible.

5. Stomach cancer

Stomach cancer remains an important cancer worldwide and is responsible for over 1 million new cases in 2018 and an estimated 783,000 deaths, equating to one in every 12 deaths globally, making it the fifth most frequently diagnosed cancer and third leading cause of cancer deaths. The rates are 2-fold higher in men than women. Although they are often reported as a single entity, gastric cancer can generally be classified into 2 topographical categories. Rates of noncardia gastric cancer (arising from distal regions) have steadily declined over the last 50 years in most populations. Cancers of the gastric cardia (arising in the area adjoining the oesophageal-gastric junction) have epidemiological characteristics more similar to those of oesophageal adenocarcinoma and important risk factors include obesity and gastroesophageal reflux disease. The incidence of these cancers is increasing particularly in high-income countries (3).

In India the age-standardized incidence rate for stomach cancer in 2016 was 5.8 per 100,000 population of which the rate was 8.1 per 100,000 population in men and 3.6 per 100,000 population in women. The crude mortality rate was 4.7 per 100,000 population with 6.3 per 100,000 population in men and 3.1 per 100,000 population in women (25). As a total, 62,600 people died of cancer stomach in 2016 of which 43,000 were men and 19,600 were women (25).

The constant decline of stomach cancer in industrialized countries is linked to improved food preservation practices; better nutrition more rich in vitamins from fresh vegetables and fruits; and less consumption of preserved, cured and salted foods. Infection with the bacterium Helicobacter pylori contributes to the risk, probably by interacting with the other factors.

Symptoms are non-specific, which explains why most of the cases are diagnosed when the disease is at an advanced stage. Patients may complain of weight loss, fatigue or gastric discomfort. Diagnosis is performed by barium X-rays and with biopsy.

This cancer is treated by surgical removal of the tumour, with or without adjuvant chemotherapy.

Stomach cancer cases have a generally poor survival prognosis, averaging no more than 20% survival after five years. If the tumour is localized to the stomach, about 60% of patients survive five years or more. However, only about 18% of all cases are diagnosed at this early stage. Screening by photofluoroscopy has been widespread in Japan since the late 1960s and mortality rates are declining. It is unclear whether this trend can be attributed to mass screening alone.

References
Once regarded as a single disease entity, diabetes is now seen as a heterogeneous group of diseases, characterized by a state of chronic hyperglycemia, resulting from a diversity of aetiologies, environmental and genetic, acting jointly (1). The underlying cause of diabetes is the defective production or action of insulin, a hormone that controls glucose, fat and amino acid metabolism. Characteristically, diabetes is a long-term disease with variable clinical manifestations and progression. Chronic hyperglycaemia, from whatever cause, leads to a number of complications – cardiovascular, renal, neurological, ocular and others such as intercurrent infections.

**Classification**

The classification adopted by WHO (2) is given in Table 1.

**Source**

Type 1 diabetes (Insulin-dependent diabetes mellitus) is the most severe form of the disease. Its onset is typically abrupt and is usually seen in individuals less than 30 years of age. It is lethal unless promptly diagnosed and treated. This form of diabetes is immune-mediated in over 90 per cent of cases and idiopathic in less than 10 per cent cases. The rate of destruction of pancreatic β cell is quite variable. Rapid in some individuals and slow in others. Type 1 diabetes is usually associated with ketosis in its untreated state. It occurs mostly in children, the Incidence is highest among 10-14 year old group, but occasionally occur in adults. It is catabolic disorder in which circulating insulin is virtually absent, plasma glucagon is elevated, and the pancreatic β cells fail to respond to all insulinogenic stimuli. Exogenous insulin is therefore required to reverse the catabolic state, prevent ketosis, reduce the hyperglycaemia, and reduce blood glucose (3).

Type 2 diabetes is much more common than type 1 diabetes. It is often discovered by chance. It is typically gradual in onset and occurs mainly in the middle-aged and elderly, frequently mild, slow to ketosis and is compatible with long survival if given adequate treatment. Its clinical picture is usually complicated by the presence of other disease processes.

Gestational diabetes is hyperglycaemia with blood glucose values above normal but below those diagnostic of diabetes, occurring during pregnancy. Women with gestational diabetes are at an increased risk of complications during pregnancy and at delivery. They and their children are also at increased risk of type 2 diabetes in the future.

Impaired glucose tolerance (IGT) describes a state intermediate — "at-risk" group — between diabetes mellitus and normality. It can only be defined by the oral glucose tolerance test (see Table 3).
Insulin resistance syndrome (Syndrome X)

In obese patients with type 2 diabetes, the association of hyperglycaemia, hyperinsulinaemia, dyslipidaemia and hypertension, which leads to coronary artery disease and stroke, may result from a genetic defect producing insulin resistance, with the latter being exaggerated by obesity. It has been proposed that insulin resistance predisposes to hyperglycaemia, which results in hyperinsulinaemia (which may or may not be of sufficient magnitude to correct the hyperglycaemia) and thus excessive insulin level then contributes to high levels of triglycerides and increased sodium retention by renal tubules, thus inducing hypertension. High levels of insulin can stimulate endothelial proliferation to initiate atherosclerosis (3).

Problem statement

WORLD

Diabetes is an "iceberg" disease. Although increase in both the prevalence and incidence of type 2 diabetes have occurred globally, they have been especially dramatic in societies in economic transition, in newly industrialized countries and in developing countries. During year 2014, the number of cases of diabetes worldwide is estimated to be around 422 million, of these more than 90 per cent are type 2 diabetes. In 2015, an estimated 1.6 million people died from consequences of high blood sugar (4). More than 60 per cent diabetes deaths occur in low and middle income countries.

The apparent prevalence of hyperglycaemia depends on the diagnostic criteria used in epidemiological surveys. The global prevalence of diabetes in 2014 was estimated to be 8.5% in adults aged 18+ years (4). The prevalence of diabetes was highest in the Eastern Mediterranean Region and the Region of the Americas (11% for both sexes) and lowest in the WHO European and Western Pacific Regions (9% for both sexes). The magnitude of diabetes and other abnormalities of glucose tolerance are considerably higher than the above estimates if the categories of 'impaired fasting' and 'impaired glucose tolerance' are also included. The estimated prevalence of diabetes was relatively consistent across the income groupings of countries. Low-income countries showed the lowest prevalence (8% for both sexes), and the upper-middle-income countries showed the highest (10% for both sexes) (5).

Unfavourable modification of lifestyle and dietary habits that are associated with urbanization are believed to be the most important factors for the development of diabetes. The prevalence of diabetes is approximately twice in urban areas than in rural population.

A bulk of evidence from studies on migrants indicates that the ethnic, presumably genetic, vulnerability of Asians manifests into diabetes when subjected to unfavourable lifestyles. Population-based surveys completed recently in Bangladesh, India and Indonesia have shown considerable increase in the prevalence rate of the disease in both urban and rural dwellers when compared to results obtained earlier.

Diabetic patients, if undiagnosed or inadequately treated, develop multiple chronic complications leading to irreversible disability and death. Coronary heart disease and stroke are more common in diabetics than in the general population. Microvascular complications like diabetic renal disease and diabetic retinopathy and neuropathy are serious health problems resulting in deterioration of the quality of life and premature death. In fact, diabetes is listed among the five most important determinants of the cardiovascular disease epidemic in Asia. Lower limb amputation are at least 10 times more common in diabetic than in non-diabetic individuals in developed countries, more than half of all non-traumatic lower limb amputations are due to diabetes (5). Metabolic disorders in pregnant diabetic women as well as those caused by gestational diabetes (diabetes diagnosed for the first time during pregnancy) pose a high health risk, to both the mother and foetus.

Unfortunately, there is still inadequate awareness about the real dimension of the problem among the general public. There is also a lack of awareness about the existing interventions for preventing diabetes and the management of complications. Inadequacies in primary health care systems, which are not designed to cope with the additional challenges posed by the chronic non-communicable diseases, result in poor detection of cases, suboptimal treatment and insufficient follow-up leading to unnecessary disabilities and severe complications, often resulting in early death.

The age-adjusted mortality rates among the people with diabetes are 1.5 to 2.5 times higher than in the general population (6). In Caucasian population, much of the excess mortality is attributable to cardiovascular disease, especially coronary heart disease; amongst Asian and American Indian population, renal disease is a major contributor (6); whereas in some developing societies, infections are an important cause of death. It is conceivable that the decline in mortality due to coronary heart disease which has occurred in many affluent countries may be halted or even reversed if rates of type 2 diabetes continue to rise. This may occur if the coronary risk factors associated with diabetes increase to the extent that the risk they mediate outweighs the benefit accrued from improvements in conventional cardiovascular risk factors, and the improved care of patients with established cardiovascular disease (6).

In addition to non-insulin dependent diabetes, which is rather silent, chronic, often unidentified killer mostly among the adult population, the insulin dependent form of the disease (type 1) makes an even more dramatic appearance in affected children. They develop symptoms of ketoacidosis and often die, since the majority do not have access to adequate medical care, and since insulin is not available or too expensive. It is estimated that the prevalence of type 1 diabetes in Asia is relatively low, accounting for about 9.7 per cent of all diabetes mellitus cases in the Region. The insulin dependent diabetes registry at Chennai (India) reported an incidence of 10.5 per 100,000 children in the age group of 10–12 years (7).

INDIA

The population in India has an increased susceptibility to diabetes mellitus. This propensity was demonstrated by multiple surveys of migrant Indians residing in Fiji, Singapore, South Africa, U.K. and USA. The rates of diabetes in migrants from the Indian subcontinent have consistently shown to exceed those of the local population.

During the year 2012 in India, the proportional mortality (% of total death, all ages) due to diabetes was about 2 per cent. The number of deaths due to diabetes in age group 30–69 was 75,900 in males and 51,700 in females and in age 70+ years about 46,800 in males and 45,600 in females. The mortality rate was about 30.2 per 100,000 population for men and 22.7 per 100,000 population for women. The number of deaths attributable to high blood
glucose in age group 30-69 was 251,300 for men and 145,700 for women (8).

National programme for prevention and control of noncommunicable diseases are operational in India and it includes diabetes and diabetes registry. For details please refer to chapter 7.

Natural history

Epidemiological determinants

1. AGENT

The underlying cause of diabetes is insulin deficiency which is absolute in type 1 diabetes and partial in type 2 diabetes. This may be due to a wide variety of mechanisms: (a) pancreatic disorders – inflammatory, neoplastic and other disorders such as cystic fibrosis, (b) defects in the formation of insulin, e.g., synthesis of an abnormal, biologically less active insulin molecule; (c) destruction of beta cells, e.g., viral infections and chemical agents, (d) decreased insulin sensitivity, due to decreased numbers of adipocyte and monocyte insulin receptors. (e) genetic defects, e.g., mutation of insulin gene; and (f) autoimmunity. Evidence is accumulating that the insulin response to glucose is genetically controlled. The overall effect of these mechanisms is reduced utilization of glucose which leads to hyperglycaemia accompanied by glycosuria.

2. HOST FACTORS

(a) AGE: Although diabetes may occur at any age, surveys indicate that prevalence rises steeply with age. Type 2 diabetes usually comes to light in the middle years of life and thereafter begins to rise in frequency. Malnutrition related diabetes affects large number of young people. The prognosis is worse in younger diabetics who tend to develop complications earlier than older diabetics. (b) SEX: In some countries (e.g., UK) the overall male–female ratio is about equal (9). In south-east Asia, an excess of male diabetics has been observed (1), but this is open to question. (c) GENETIC FACTORS: The genetic nature of diabetes is undisputed. Twin studies showed that in identical twins who developed type 2 diabetes, concordance was approximately 90 per cent (2), thus demonstrating a strong genetic component. In type 1 diabetes, the concordance was only about 50 per cent indicating that type 1 diabetes is not totally a genetic entity. (d) GENETIC MARKERS: Type 1 diabetes is associated with HLA-B8 and B15, and more powerfully with HLA–DR3 and DR4. The highest risk of type 1 diabetes is carried by individuals with both DR3 and DR4. On the other hand type 2 diabetes is not HLA–associated (2). (e) IMMUNE MECHANISMS: There is some evidence of both cell-mediated and of humoral activity against islet cells. Some people appear to have defective immunological mechanisms, and under the influence of some environmental "trigger", attack their own insulin producing cells. (f) OBESITY: Obesity particularly central adiposity has long been accepted as a risk factor for type 2 diabetes and the risk is related to both the duration and degree of obesity. The association has been repeatedly demonstrated in longitudinal studies in different populations, with a striking gradient of risk apparent with increasing level of BMI, adult weight gain, waist circumference or waist to hip ratio. Indeed waist circumference or waist to hip ratio (reflecting abdominal or visceral adiposity) are more powerful determinants of subsequent risk of type 2 diabetes than BMI (6). Central obesity is also an important determinant of insulin resistance, the underlying abnormality in most cases of type 2 diabetes. In some instances obesity reduces the number of insulin receptors on target cells. Voluntary weight loss improves insulin sensitivity and in several randomized controlled trials has shown to reduce the risk of progression from impaired glucose tolerance to type 2 diabetes (10, 11). However, many obese subjects are not diabetic. Thus obesity by itself is inadequate to account for, all, or even most, cases of type 2 diabetes; physical inactivity and/or deficiencies of specific nutrients may also be involved (2). Obesity appears to play no role in type 1 diabetes pathogenesis (12). (g) MATERNAL DIABETES: Offspring of diabetic pregnancies including gestational diabetes are often large and heavy at birth, tend to develop obesity in childhood and are at high risk of developing type 2 diabetes at an early age. Those born to mothers after they have developed diabetes have a three-fold higher risk of developing diabetes than those born before. Maternal diabetes associated with intrauterine growth retardation and low birth weight, when associated with rapid growth catch-up later on, appears to increase the risk of subsequent diabetes in the child (6).

3. ENVIRONMENTAL RISK FACTORS

Susceptibility to diabetes appears to be unmasked by a number of environmental factors acting on genetically susceptible individuals. They include: (a) SEDENTARY LIFESTYLE: Sedentary life style appears to be an important risk factor for the development of type 2 diabetes. Lack of exercise may alter the interaction between Insulin and its receptors and subsequently lead to type 2 diabetes (2). (b) DIET: A high saturated fat intake has been associated with a higher risk of impaired glucose tolerance, and higher fasting glucose and insulin levels (6). Higher proportions of saturated fatty acids in serum lipid or muscle phospholipid have been associated with higher fasting insulin, lower insulin sensitivity and a higher risk of type 2 diabetes. Higher unsaturated fatty acids from vegetable sources and polyunsaturated fatty acids have been associated with reduced risk of type 2 diabetes and lower fasting and 2-hour glucose concentrations. Higher proportions of long-chain polyunsaturated fatty acids in skeletal muscle phospholipids have been associated with increased insulin sensitivity (6). In human intervention studies, replacement of saturated by unsaturated fatty acids leads to improved glucose tolerance and enhanced insulin sensitivity. However, long chain polyunsaturated fatty acids do not appear to confer additional benefit over monounsaturated fatty acids. When total fat intake is high (greater than 37 per cent of total energy), altering the quality of dietary fat appears to have little effect (13). (c) DIETARY FIBRE: In many controlled experimental studies, high intakes of dietary fibre have been shown to result in reduced blood glucose and insulin levels in people with type 2 diabetes and impaired glucose tolerance (14). Moreover an increased intake of wholegrain cereals, vegetables and fruits (all rich in NSP) was a feature of diets in randomized controlled trials. Thus the evidence for a potential protective effect of dietary fibre appears strong. A minimum daily intake of 20 grams of dietary fibre is recommended (6). Table 2 shows a summary of lifestyle and dietary factors associated with diabetes. (d) MALNUTRITION: Malnutrition (PEM) in early infancy and childhood may result in partial failure of β-cell function. Damage to beta cells may well explain the associated impaired carbohydrate tolerance in kwashiorkor (2). (e) ALCOHOL: Excessive intake of alcohol can increase the risk of diabetes by damaging the pancreas.

a Includes gestational diabetes.
b As a global public health recommendation, infants should be exclusively breast-fed for the first six months of life to achieve optimal growth, development and health.

In the past, the commonest approach to diabetes screening was a preliminary, semi-quantitative test for glucose in a urine sample, followed by an oral glucose tolerance test for those found to have glycosuria. Most studies now confirm that although glucose is found in urine in the most severe cases of diabetes, it is often absent in milder forms of the disease, and such cases are likely to be missed by urine test. This is known as lack of “sensitivity”. To be more precise, the sensitivity of the test (i.e., proportion of people with disease who have a positive test) varies between 10–50 per cent. The lack of sensitivity means that many diabetics would have been missed if this had been the only test. That is, the test yields too many “false-negatives”. Further, glycosuria may be found in perfectly normal people; this gives rise to “false-positives”. Since the specificity of the test is over 90 per cent, the yield of false-positives is not very high. For these reasons, urine testing is not considered an appropriate tool for case-finding or epidemiological surveys of the population (2).

2. Blood sugar testing

Because of the inadequacies of urine examination, “standard oral glucose test” remains the cornerstone of diagnosis of diabetes. Mass screening programmes have used glucose measurements of fasting, postprandial or random blood sample. The measurement of glucose levels in random blood samples is considered unsatisfactory for epidemiological use; at the most, it can give only a crude estimate of the frequency of diabetes in a population (2). The fasting value alone is considered less reliable since true fasting cannot be assured and spurious diagnosis of diabetes may more readily occur. Therefore, for epidemiological purposes, the 2-hour value after 75 g oral glucose may be used either alone or with the fasting value (2). Automated biochemistry has now made it possible to screen thousands of samples for glucose estimation. The criteria for the diagnosis of diabetes, proposed by WHO, are given in Table 3.

Target population

Screening of the whole population for diabetes is not considered a rewarding exercise (17, 18). However, screening of “high-risk” groups is considered more appropriate. These groups are: (i) those in the age group 40 and over; (ii) those with a family history of diabetes; (iii) the obese; (iv) women who have had a baby weighing more

than 4.5 kg (or 3.5 kg in constitutionally small populations); (v) women who show excess weight gain during pregnancy; and (vi) patients with premature atherosclerosis.

PREVENTION AND CARE

1. Primary prevention

Two strategies for primary prevention have been suggested: (a) population strategy, and (b) high-risk strategy (2).

a. POPULATION STRATEGY

The scope for primary prevention of type 1 diabetes is limited on the basis of current knowledge and is probably not appropriate (2). However, the development of prevention programmes for type 2 diabetes based on elimination of environmental risk factors is possible. There is pressing need for primordial prevention — that is, prevention of the emergence of risk factors in countries in which they have not yet appeared. The preventive measures comprise maintenance of normal body weight through adoption of healthy nutritional habits and physical exercise. The nutritional habits include an adequate protein intake, a high intake of dietary fibre and avoidance of sweet foods. Elimination of other well defined factors such as protein deficiency and food toxins may be considered in some populations. These measures should be fully integrated into other community-based programmes for the prevention of non-communicable diseases (e.g., coronary heart disease).

b. HIGH-RISK STRATEGY

There is no special high-risk strategy for type 1 diabetes. At present, there is no practical justification for genetic counselling as a method of prevention (2).

Since NIDDM appears to be linked with sedentary lifestyle, over-nutrition and obesity, correction of these may reduce the risk of diabetes and its complications. Since alcohol can indirectly increase the risk of diabetes, it should be avoided. Subjects at risk should avoid diabetogenic drugs like oral contraceptives. It is wise to reduce factors that promote atherosclerosis, e.g., smoking, high blood pressure, elevated cholesterol and high triglyceride levels. These programmes may most effectively be directed at target population groups.

2. Secondary prevention

When diabetes is detected, it must be adequately treated. The aims of treatment are: (a) to maintain blood glucose levels as close within the normal limits as is practicable (see Table 3), and (b) to maintain ideal body weight. Treatment is based on (a) diet alone — small balanced meals more frequently, (b) diet and oral antidiabetic drugs, or (c) diet and insulin. Good control of blood glucose protects against the development of complications. Please see in chapter 10 "Nutrition and health" under title "Nutritional factors in selected diseases" for details.

Proper management of the diabetic is most important to prevent complications. Routine checking of blood sugar, of urine for proteins and ketones, of blood pressure, visual acuity and weight should be done periodically. The feet should be examined for any detectable blood circulation (Doppler ultrasound probes are advised), loss of sensation and the health of the skin. Primary health care is of great importance to diabetic patients since most care is obtained at this level.

Glycosylated haemoglobin: There should be an estimation of glycated (glycosylated) haemoglobin at half-yearly intervals. This test provides a long-term index of glucose control. This test is based on the following rationale: glucose in the blood is complexed to a certain fraction of haemoglobin to an extent proportional to the blood glucose concentration. The percentage of such glycospated haemoglobin reflects the mean blood glucose levels during the red cell life-time (i.e., about the previous 2–3 months) (19).

Self-care: A crucial element in secondary prevention is self care. That is, the diabetic should take a major responsibility for his own care with medical guidance — e.g., adherence to diet and drug regimens, examination of his own urine and where possible blood glucose monitoring; self-administration of insulin, abstinence from alcohol, maintenance of optimum weight, attending periodic check-ups, recognition of symptoms associated with glycosuria and hypoglycaemia, etc.

Table 4 shows some of the individual interventions in diabetes with evidence of efficacy.

Home blood glucose monitoring: Assessment of control has been greatly aided by the recent facility of immediate, reasonably accurate, capillary blood glucose measurements either by one of the many meters now available or the direct reading Haemoglukotest strips (20).

The patient should carry an identification card showing his name, address, telephone number (if any) and the details of treatment he is receiving. In short, he must have a working knowledge of diabetes. All these mean education of patients and their families to optimize the effectiveness of primary health care services.

3. Tertiary prevention

Diabetes is major cause of disability through its complications, e.g., blindness, kidney failure, coronary thrombosis, gangrene of the lower extremities, etc. The main

objective at the tertiary level is to organize specialized clinics (Diabetic clinics) and units capable of providing diagnostic and management skills of a high order. There is a great need to establish such clinics in large towns and cities (21). The tertiary level should also be involved in basic, clinical and epidemiological research. It has also been recommended that local and national registries for diabetics should be established (2).

Obesity

Obesity may be defined as an abnormal growth of the adipose tissue due to an enlargement of fat cell size (hypertrophic obesity) or an increase in fat cell number (hyperplastic obesity) or a combination of both (1). Obesity is often expressed in terms of body mass index (BMI) (see Table 1). Overweight is usually due to obesity but can arise from other causes such as abnormal muscle development or fluid retention (2).

However, obese individuals differ not only in the amount of excess fat that they store, but also in the regional distribution of the fat within the body. The distribution of fat induced by the weight gain affects the risk associated with obesity, and the kind of disease that results. It is useful therefore, to be able to distinguish between those at increased risk as a result of "abdominal fat distribution" or "android obesity" from those with the less serious "gynoid" fat distribution, in which fat is more evenly and peripherally distributed around the body.

Obesity is perhaps the most prevalent form of malnutrition. As a chronic disease, prevalent in both developed and developing countries, and affecting children as well as adults, it is now so common that it is replacing the more traditional public health concerns including undernutrition. It is one of the most significant contributors to ill health. For industrialized countries, it has been suggested that such increase in body weight have been caused primarily by reduced levels of physical activity, rather than by changes in food intake or by other factors. It is extremely difficult to assess the size of the problem and compare the prevalence rates in different countries as no exact figures are available and also because the definitions of obesity are not standardized.

Overweight and obesity are the fifth leading risk of global deaths. Worldwide, obesity has more than doubled since 1980. In 2016, more than 1.9 billion adults, 18 years and older, were overweight. Of these over 650 million men and women were obese (3).

In 2016, more than 41 million children under 5 years of age were overweight or obese. Once considered a high-
income country problem, overweight and obesity are now rising in low-and middle-income countries, particularly in urban settings (3A). Close to 30 million overweight children are living in developing and 10 million in developed countries (3A). Childhood obesity is associated with a higher chance of obesity, premature death and disability in adulthood. In addition, it is associated with future risk of increased breathing difficulties, increased risk of fractures, hypertension, early markers of cardiovascular disease, insulin resistance and psychological effects.

At least 3.4 million adults die each year as a result of being overweight or obese. In addition, 44 per cent of the diabetes burden, 23 per cent of ischaemic heart disease burden and between 7 to 41 per cent of certain cancer burdens are attributable to overweight and obesity (3A). Overweight and obesity are linked to more deaths worldwide than underweight.

In India, the non-communicable risk factor survey phase 2 was carried out in the year 2007–2008, in the states of Andhra Pradesh, Kerala, Madhya Pradesh, Maharashtra, Tamil Nadu, Uttar Pradesh and Mizoram. The survey shows high prevalence of overweight in all age groups except in 15–24 years group. Overweight prevalence was highest among females than males and in urban areas than in rural areas. Low prevalence was recorded among lower level of education (illiterate and primary level), and in people whose occupation was connected with agriculture or manual work (4).

In India, 1.3 per cent males and 2.5 per cent females aged more than 20 years were obese in the year 2008 (5).

As obesity is a key risk factor in natural history of other chronic and non-communicable diseases, the typical time sequence of emergence of chronic diseases following the increased prevalence of obesity is important in public health planning. The first adverse effects of obesity to emerge in population in transition are hypertension, hyperlipidaemia and glucose intolerance, while coronary heart disease and the long-term complications of diabetes, such as renal failure begin to emerge several years (or decades) later (7). It is matter of time before same mortality rates for such diseases will be seen in developing countries as those prevailing 30 years ago in industrialized countries (8).

Epidemiological determinants

The aetiology of obesity is complex, and is one of multiple causation:

(a) AGE: Obesity can occur at any age, and generally increases with age. Infants with excessive weight gain have an increased incidence of obesity in later life (9). About one-third of obese adults have been so since childhood (11). It has been well established that most adipose cells are formed early in life and the obese infant lays down more of these cells (hyperplastic obesity) than the normal infant. Hyperplastic obesity in adults is extremely difficult to treat with conventional methods.

(b) SEX: Women generally have higher rate of obesity than men, although men may have higher rates of overweight. In the Framingham, USA study, men were found to gain most weight between the ages of 29 and 35 years, while women gain most between 45 and 49 years of age (10), i.e. at menopausal age. It has been claimed that women’s BMI increases with successive pregnancies. The recent evidence suggested that this increase is likely to be, on an average, about 1 kg per pregnancy. On the other hand in many developing countries, consecutive pregnancies at short intervals are often associated with weight loss rather than weight gain (3).

(c) GENETIC FACTORS: There is a genetic component in the aetiology of obesity. Twin studies have shown a close correlation between the weights of identical twins even when they are reared in dissimilar environments (11). The profile of fat distribution is also characterized by a significant heritability level of the order of about 50 per cent of the total human variation. Recent studies have shown that the amount of abdominal fat was influenced by a genetic component accounting for 50–60 per cent of the individual differences (8).

(d) PHYSICAL INACTIVITY: There is convincing evidence that regular physical activity is protective against unhealthy weight gain. Where as sedentary lifestyle particularly sedentary occupation and inactive recreation such as watching television promote it, physical activity and physical fitness are important modifiers of mortality and morbidity related to overweight and obesity (12). In some individuals a major reduction in activity without the compensatory decrease in habitual energy intake may be the major cause of increased obesity, e.g. in athletes when they retire and in young people who sustain injuries etc. Physical inactivity may cause obesity, which in turn restricts activity. This is a vicious circle. It is the reduced energy output that is probably more important in the aetiology of obesity than used to be thought (11).

(e) SOCIO-ECONOMIC STATUS: The relationship of obesity to social class has been studied in some detail. There is a clear direct relationship between socio-economic status and obesity. Within some affluent countries, however, obesity has been found to be more prevalent in the lower socio-economic groups.

(f) EATING HABITS: Eating habits (e.g., eating in between meals, preference to sweets, refined foods and fats) are established very early in life. The composition of the diet, the periodicity with which it is eaten and the amount of energy derived from it are all relevant to the aetiology of obesity. A diet containing more energy than needed may lead to prolonged post-prandial hyperlipidaemia and to deposition of triglycerides in the adipose tissue resulting in obesity (13). Nowadays television and print media is playing an important role in producing obesity by heavy advertisement of fast food outlets of energy-dense, micronutrient poor food and beverages (usually classified under the “eat least” category in diet guidelines) of multinational corporations, which influence the daily eating habits. The consumer demand by itself may be influenced by advertising, marketing, culture, fashion and convenience (8). It has been calculated that a child whose energy requirement is 2000 kcal/day and who consumes 100 kcal/day extra will gain about 5 kg a year (10). The accumulation of one kilo of fat corresponds to 7,700 kcal of energy (14).

(g) PSYCHOSOCIAL FACTORS: Psychosocial factors (e.g., emotional disturbances) are deeply involved in the aetiology of obesity. Overeating may be a symptom of depression, anxiety, frustration and loneliness in childhood as it is in adult life. Excessively obese individuals are usually withdrawn, self-conscious, lonely and secret eaters. An insight into the circumstances in which the obesity has developed is essential for planning the most suitable management.

At least 3.4 million adults die each year as a result of being overweight or obese. In addition, 44 per cent of the diabetes burden, 23 per cent of ischemic heart disease burden and between 7 to 41 per cent of certain cancer burdens are attributable to overweight and obesity (3A). Overweight and obesity are linked to more deaths worldwide than underweight.

In India, the non-communicable risk factor survey phase 2 was carried out in the year 2007–2008, in the states of Andhra Pradesh, Kerala, Madhya Pradesh, Maharashtra, Tamil Nadu, Uttar Pradesh and Mizoram. The survey shows high prevalence of overweight in all age groups except in 15–24 years group. Overweight prevalence was highest among females than males and in urban areas than in rural areas. Low prevalence was recorded among lower level of education (illiterate and primary level), and in people whose occupation was connected with agriculture or manual work (4).

In India, 1.3 per cent males and 2.5 per cent females aged more than 20 years were obese in the year 2008 (5).

As obesity is a key risk factor in natural history of other chronic and non-communicable diseases, the typical time sequence of emergence of chronic diseases following the increased prevalence of obesity is important in public health planning. The first adverse effects of obesity to emerge in population in transition are hypertension, hyperlipidaemia and glucose intolerance, while coronary heart disease and the long-term complications of diabetes, such as renal failure begin to emerge several years (or decades) later (7). It is matter of time before same mortality rates for such diseases will be seen in developing countries as those prevailing 30 years ago in industrialized countries (8).

Epidemiological determinants

The aetiology of obesity is complex, and is one of multiple causation:

(a) AGE: Obesity can occur at any age, and generally increases with age. Infants with excessive weight gain have an increased incidence of obesity in later life (9). About one-third of obese adults have been so since childhood (11). It has been well established that most adipose cells are formed early in life and the obese infant lays down more of these cells (hyperplastic obesity) than the normal infant. Hyperplastic obesity in adults is extremely difficult to treat with conventional methods.

(b) SEX: Women generally have higher rate of obesity than men, although men may have higher rates of overweight. In the Framingham, USA study, men were found to gain most weight between the ages of 29 and 35 years, while women gain most between 45 and 49 years of age (10), i.e. at menopausal age. It has been claimed that women’s BMI increases with successive pregnancies. The recent evidence suggested that this increase is likely to be, on an average, about 1 kg per pregnancy. On the other hand in many developing countries, consecutive pregnancies at short intervals are often associated with weight loss rather than weight gain (3).

(c) GENETIC FACTORS: There is a genetic component in the aetiology of obesity. The profile of fat distribution is also characterized by a significant heritability level of the order of about 50 per cent of the total human variation. Recent studies have shown that the amount of abdominal fat was influenced by a genetic component accounting for 50–60 per cent of the individual differences (8).

(d) PHYSICAL INACTIVITY: There is convincing evidence that regular physical activity is protective against unhealthy weight gain. Where as sedentary lifestyle particularly sedentary occupation and inactive recreation such as watching television promote it, physical activity and physical fitness are important modifiers of mortality and morbidity related to overweight and obesity (12). In some individuals a major reduction in activity without the compensatory decrease in habitual energy intake may be the major cause of increased obesity, e.g. in athletes when they retire and in young people who sustain injuries etc. Physical inactivity may cause obesity, which in turn restricts activity. This is a vicious circle. It is the reduced energy output that is probably more important in the aetiology of obesity than used to be thought (11).

(e) SOCIO-ECONOMIC STATUS: The relationship of obesity to social class has been studied in some detail. There is a clear direct relationship between socio-economic status and obesity. Within some affluent countries, however, obesity has been found to be more prevalent in the lower socio-economic groups.

(f) EATING HABITS: Eating habits (e.g., eating in between meals, preference to sweets, refined foods and fats) are established very early in life. The composition of the diet, the periodicity with which it is eaten and the amount of energy derived from it are all relevant to the aetiology of obesity. A diet containing more energy than needed may lead to prolonged post-prandial hyperlipidaemia and to deposition of triglycerides in the adipose tissue resulting in obesity (13). Nowadays television and print media is playing an important role in producing obesity by heavy advertisement of fast food outlets of energy-dense, micronutrient poor food and beverages (usually classified under the “eat least” category in diet guidelines) of multinational corporations, which influence the daily eating habits. The consumer demand by itself may be influenced by advertising, marketing, culture, fashion and convenience (8). It has been calculated that a child whose energy requirement is 2000 kcal/day and who consumes 100 kcal/day extra will gain about 5 kg a year (10). The accumulation of one kilo of fat corresponds to 7,700 kcal of energy (14).

(g) PSYCHOSOCIAL FACTORS: Psychosocial factors (e.g., emotional disturbances) are deeply involved in the aetiology of obesity. Overeating may be a symptom of depression, anxiety, frustration and loneliness in childhood as it is in adult life. Excessively obese individuals are usually withdrawn, self-conscious, lonely and secret eaters. An insight into the circumstances in which the obesity has developed is essential for planning the most suitable management.
There is good evidence that abdominal obesity is important in the development of insulin resistance, and in the metabolic syndrome (hyperinsulinaemia, dyslipidaemia, glucose intolerance, and hypertension) that link obesity with cardiovascular disease. Furthermore, intra-abdominal adipocytes are located upstream from liver in the portal circulation. This means that there is a marked increase in the flux of nonesterified fatty acid to the liver via the portal blood in patients with abdominal obesity.

Assessment of obesity

Before we consider assessment of obesity, it will be useful to first look at body composition as under:

1. **BODY WEIGHT**

   Body weight, though not an accurate measure of excess fat, is a widely used index. In epidemiological studies it is conventional to accept + 2 SD (standard deviations) from the median weight for height as a cut-off point for overweight and + 3 SD for obesity.
For adults, some people calculate various other indicators such as (10):

1. **Body mass index (Quetelet's index)**
   \[
   \text{BMI} = \frac{\text{Weight (kg)}}{\text{Height}^2 (m)}
   \]

2. **Ponderal index**
   \[
   \text{PI} = \frac{\text{Height (cm)}}{\text{Cube root of body weight (kg)}}
   \]

3. **Brocca index**
   \[
   \text{Brocca} = \text{Height (cm)} - 100
   \]
   For example, if a person's height is 160 cm, his ideal weight is \((160 - 100) = 60\ kg\)

4. **Lorentz's formula**
   \[
   \text{Lorentz} = \frac{\text{Ht (cm)} - 100}{\text{Ht (cm)} - 150}
   \]
   \(2\) (women) or \(4\) (men)

5. **Corpulence index**
   \[
   \frac{\text{Actual weight}}{\text{Desirable weight}}
   \]
   This should not exceed 1.2

The body mass index (BMI) and the Brocca index are widely used. A FAO/WHO/UNU Report gives the much needed reference tables for body mass index (see Table 1) which can be used internationally as reference standards for assessing the prevalence of obesity in a community.

2. **SKINFOLD THICKNESS**

A large proportion of total body fat is located just under the skin. Since it is most accessible, the method most used is the measurement of skinfold thickness. It is a rapid and "non-invasive" method for assessing body fat. Several varieties of callipers (e.g., Harpenden skin callipers) are available for the purpose. The measurement may be taken at all the four sites — mid-triceps, biceps, subscapular and suprailliac regions. The sum of the measurements should be less than 40 mm in boys and 50 mm in girls (15). Unfortunately standards for subcutaneous fat do not exist for comparison. Further, in extreme obesity, measurements may be impossible. The main drawback of skinfold measurements is their poor repeatability.

3. **WAIST CIRCUMFERENCE AND WAIST: HIP RATIO (WHR)**

Waist circumference is measured at the mid point between the lower border of the rib cage and the iliac crest. It is a convenient and simple measurement that is unrelated to height, correlates closely with BMI and WHR and is an approximate index of intra-abdominal fat mass and total body fat. Changes in waist circumference reflect changes in risk factors for cardiovascular disease and other forms of chronic diseases. There is an increased risk of metabolic complications for men with a waist circumference \(\geq 102\ cm\) and women with a waist circumference \(\geq 88\ cm\) (12).

Over the past 10 years or so, it has become accepted that a high WHR (\(> 1.0\) in men and \(> 0.85\) in women) indicates abdominal fat accumulation.

4. **OTHERS**

In addition to the above, three well-established and more accurate measurements are used for the estimation of body fat. They are measurement of total body water, of total body potassium and of body density. The techniques involved are relatively complex and cannot be used for routine clinical purposes or for epidemiological studies (8). The introduction of measuring fat cells has opened up a new field in obesity research.

**Hazards of obesity**

Obesity is a health hazard and a detriment to well-being which is reflected in the increased morbidity and mortality:

(a) **INCREASED MORBIDITY**

Obesity is a positive risk factor in the development of hypertension, diabetes, gall bladder disease and coronary heart disease and certain types of cancers, especially the hormonally related and large bowel cancers. There are in addition, several associated diseases, which, although not usually fatal, cause a great deal of morbidity in the community, e.g., varicose veins, abdominal hernia, osteoarthritis of the knees, hips and lumbar spine, flat feet and psychological stresses particularly during adolescence. Obese persons are exposed to increased risk from surgery. Obesity may lead to lowered fertility. Table 3 shows the relative risk of health problems associated with obesity.

(b) **INCREASED MORTALITY**

The Framingham Heart Study in United States showed a dramatic increase in sudden death among men more than 20 per cent overweight as compared with those with normal weight. The increased mortality is brought about mainly by the increased incidence of hypertension and coronary heart disease. There is also an excess number of deaths from renal diseases. Obesity lowers life expectancy. More information is needed about the relationship between different degrees of obesity and morbidity and mortality. Please see in chapter 10 under heading "Nutritional factors in selected diseases" for dietary factors of obesity.

**Prevention and control**

Weight control is widely defined as approaches to maintaining weight within the 'healthy' (i.e. 'normal' or 'acceptable') range of body mass index of 18.5 to 24.9 kg/m².
throughout adulthood (WHO Expert Committee, 1995). It should also include prevention of weight gain of more than 5 kg in all people. In those who are already over-weight, a reduction of 5–10 per cent of body weight is recommended as an initial goal (7).

Prevention of obesity should begin in early childhood. Obesity is harder to treat in adults than it is in children. The control of obesity centres around weight reduction. This can be achieved by dietary changes, increased physical activity and a combination of both. (a) DIETARY CHANGES: The following dietary principles apply both to prevention and treatment: the proportion of energy-dense foods such as simple carbohydrates and fats should be reduced; the fibre content in the diet should be increased through the consumption of common un-refined foods; adequate levels of essential nutrients in the low energy diets (most conventional diets for weight reduction are based on 1000 kcal daily model for an adult) should be ensured, and reducing diets should be as close as possible to existing nutritional patterns (16). The most basic consideration is that the food energy intake should not be greater than what is necessary for energy expenditure. It requires modification of the patient’s behaviour and strong motivation to lose weight and maintain ideal weight. Unfortunately, most attempts to reduce weight in obese persons by dietary advice remain unsuccessful. (b) INCREASED PHYSICAL ACTIVITY: This is an important part of weight reducing programme. Regular physical exercise is the key to an increased energy expenditure. (c) OTHERS: Appetite suppressing drugs have been tried in the control of obesity. They are generally inadequate to produce massive weight loss in severely obese patients. Surgical treatment (e.g., gastric bypass, gastroplasty, jaw-wiring, to eliminate the eating of solid food have all been tried with limited success (17). In short, one should not expect quick or even tangible results in all cases from obesity prevention programmes. Health education has an important role to play in teaching the people how to reduce overweight and prevent obesity. A fruitful approach will be to identify those children who are at risk of becoming obese and find way of preventing it.

References
5. Glaucoma, 2 per cent; and
6. Age-related macular degeneration, 4 per cent;
About 82 per cent of all people who are visually impaired are aged 50 years and older, while this age group comprises about 20 per cent of the world’s population. With an increasing elderly population in many countries, more people will be at risk of age-related visual impairment. An estimated 19 million children are visually impaired. Of these, 12 million children are visually impaired due to refractive errors, a condition that could be easily diagnosed and corrected. 1.4 million are irreversibly blind for the rest of their lives (4).

The most frequent causes of blindness in developed countries are accidents, glaucoma, diabetes, vascular diseases (hypertension), cataract and degeneration of ocular tissues especially of the retina, and hereditary conditions.

In South-East Asia Region, cataract is the single most common cause of blindness being responsible for 50–80 per cent of all blindness. Uncorrected refractive errors are being increasingly recognized as a cause of blindness and low vision. Vitamin A deficiency, which has been responsible for most childhood blindness in the Region is gradually declining. The emerging causes of blindness include glaucoma, age-related macular degeneration, diabetic retinopathy, corneal ulcer and ocular trauma (5).

Among the leading causes of childhood blindness in the region are xerophthalmia, congenital cataract, congenital glaucoma and optic atrophy due to meningitis, retinopathy of prematurity, and uncorrected refractive errors. Xerophthalmia is largely under control with vitamin A distribution in immunization programmes.

There are an estimated 3–4 million persons blind, due to corneal opacity. With declining incidence of trachoma and xerophthalmia, the consequences of ocular trauma and corneal ulceration are emerging as important causes. According to an estimate, 6.5 million people are affected with, and 1.3 million eyes become blind due to corneal ulcer every year in the Region (5). Trachoma remains an important cause in pockets in some countries although its importance as a cause of blindness has declined over the years (6).

Overall, visual impairment worldwide has decreased since the early 1990s. This decrease is principally the result of a reduction of visual impairment from infectious diseases through public health action, overall socio-economic development, increased availability of eye care services and awareness of the general population about solution to the problems related to vision impairment (surgery, refraction devices, etc.). However, it is estimated that the number of people with vision impairment could triple due to population growth and ageing (4).

INDIA

India has changed its over four-decade-old definition of blindness, bringing it in line with the WHO criteria. According to the new definition, a person who is unable to count fingers from a distance of three meters would be considered blind as against the earlier stipulation of six meters, which was adopted in 1976. The notification in this regard has been issued by the Union Health Ministry.

According to this definition, the population of blind people in India will reduce from 1.20 crore (as per National Blindness Survey 2007 data) to 80 Lacs (7).

The nomenclature of the programme is also changed from “National Programme for Control of Blindness” to “National Programme for Control of Blindness and visual impairment” (7).

The prevalence of blindness according to rapid national survey on blindness 2006–2007 was 1.0 per cent. In the current survey (2015–2018) the projected prevalence rate is 0.45 per cent (8).

The National Survey on Blindness 2006–07 conducted in the country recognized the main causes responsible for visual impairment and blindness. As shown in Table 1, the principal cause of blindness in India today is cataract, responsible for about 62.6 per cent of all cases. Cataract occurs more frequently with advancing age. Senile cataract occurs a decade earlier in India relative to Europe and America. Uncorrected refractive error are responsible for about 19.7 per cent of blindness; overall prevalence of glaucoma was about 5.8 per cent; posterior segment pathology accounts for about 4.7 per cent cases (9). In a camp based study, glaucoma prevalence was found to be about 3.07 per cent with a slight female preponderance (males 2.9 per cent and females 3.19 per cent). Primary open angle glaucoma was more common (about 1.7 per cent) than primary angle closure glaucoma (0.73 per cent) (8). In the others group, injuries as a cause of blindness accounts for 1.2 per cent (10). There is evidence that injuries are on the increase due to increase in cottage industry (e.g. carpentry, blacksmith, stone crushing, chiselling and hammering and chopping wood), and rapid industrialization in the country. The other causes in this group includes congenital disorder, uveitis, retina detachment, tumours, diabetes, hypertension, diseases of the nervous system, leprosy, etc.

Source : (8)

Retinopathy of prematurity (ROP) is emerging as an important cause of childhood blindness. With the advent of hyperbaric oxygen and opening of large number of private and government NICUs, the survival of the premature babies (born before 30 weeks of gestation and 1500 grams of weight at birth) has improved considerably. These babies are at risk of developing ROP and there is dire necessity to create awareness not only in public but also amongst ophthalmologists and paediatricians to detect and treat ROP in time.

Epidemiological determinants

(a) AGE : About 30 per cent of the blind in India are said to lose their eyesight before they reach the age of 20 years, and many under the age of 5 years. Refractive error, trachoma, conjunctivitis and malnutrition (vitamin A deficiency) are important causes of blindness among children and the younger age groups; cataract, refractive error, glaucoma and diabetes are causes of blindness in middle age; accidents and injuries can occur in all age groups, but more importantly in the age group 20 to 40.
Changin eoncepts in eye health care

Recent years have witnessed a change from acute intervention (cure) typical of clinical ophthalmology to comprehensive eye-health care which includes the following concepts:

1. Primary eye care

One of the most significant developments in the field of eye health care over the last few years has been the concept of primary eye care, that is, the inclusion of an eye-care component in primary health care system. The idea of primary eye care, as one of the main ingredients of a primary health care approach to blindness, has rapidly gained acceptance all over the world. It is today recognized as a model for eye care at the community level. The promotion and protection of eye health, together with on-the-spot treatment for the commonest eye conditions, is one of the cornerstone of primary eye care. The final objective of primary eye care is to increase the coverage and quality of eye health care through primary health care approach and thereby improve the utilization of existing resources.

2. Epidemiological approach

The epidemiological approach which involves studies at the population level has been recognized. It focuses, among other things, on the measurement of the incidence, prevalence of diseases and their risk factors. The local epidemiological situation will determine the action needed.

3. Team concept

In many developing countries, there is only one eye specialist for more than a million people. Increasingly, therefore, health care systems use auxiliary health personnel to fill many gaps. In India this gap is filled by village health workers, ophthalmic assistants, multi-purpose workers, and voluntary agencies.

4. Establishment of national programmes

Another important development in connection with the prevention of blindness has been the establishment of national programmes. Many of these programmes were first started by voluntary agencies concerned with blindness prevention (e.g., eye camps) and some of them focused on a single disease, such as trachoma. The increasing recognition of the primary health care approach to blindness resulted in the establishment of national programmes for the prevention of blindness from all causes.

Prevention of blindness

The concept of avoidable blindness (i.e., preventable or curable blindness) has gained increasing recognition during recent years. A great many of the causes of blindness lend themselves to prevention and/or control — whether by improving nutrition, by treating cases of infectious diseases, or by controlling the organisms which cause infections, or by improving safety conditions — particularly on the roads, at work or in the home.

The components for action in national programmes for the prevention of blindness comprise the following:

1. INITIAL ASSESSMENT

The first step is to assess the magnitude, geographic distribution and causes of blindness within the country or region by prevalence surveys. This knowledge is essential for setting priorities and development of appropriate intervention programmes.

2. METHODS OF INTERVENTION (14)

(a) Primary eye care

A wide range of eye conditions (e.g., acute conjunctivitis,ophthalmia neonatorum, trachoma, superficial foreign bodies, xerophthalmia) can be treated at the grass-root level by locally trained primary health workers (e.g., village health guides, multi-purpose workers) who are the first to make contact with the community. For this purpose, they are provided with essential drugs such as topical tetracycline, vitamin A capsules, eye bandages, shields, etc. They are also trained to refer difficult cases (e.g., corneal ulcer, penetrating foreign bodies, painful eye conditions and infections which do not respond to treatment) to the nearest PHC or district hospital. Their activities also involve promotion of personal hygiene, sanitation, good dietary habits and safety in general. Currently, there is one village health guide for 1000 population and 2 multipurpose workers for 5000 population in India.

In short, primary eye care is based firmly in primary health care which is "...essential health care......made universally accessible to individuals and families in the community through their full participation and at a cost that the community and country can afford ..." (Article VI of the Declaration of Alma Ata, 1978).

(b) Secondary care

Secondary care involves definitive management of common blinding conditions such as cataract, trichiasis, entropion, ocular trauma, glaucoma, etc. This care is provided in PHCs and district hospitals where eye departments or eye clinics are established. The secondary care may involve the use of mobile eye clinics. For instance, cataract accounts for over 62 per cent of blindness in India. The eye camp approach to make cataract surgery available
has been highly successful, and has received wide popular support. Apart from cataract operations, these camps undertake general health surveys for the early detection of visual defects as well as education of the masses. For mobile services to be effective, there must be good community participation in the programme. Adequate follow-up and evaluation must also be provided. The "mobile units", though valuable, lack permanence and are being utilized as part of a comprehensive strategy for eye care. The great advantage of this strategy is, it is problem-specific and makes the best use of local resources and provides inexpensive eye care to the population at the peripheral level (15).

(c) Tertiary care
These services are usually established in the national or regional capitals and are often associated with Medical Colleges and Institutes of Medicine. They provide sophisticated eye care such as retinal detachment surgery, corneal grafting and other complex forms of management not available in secondary centres. The majority of States in India has passed the Corneal Grafting Acts which have helped the establishment of Eye Banks. Other measures of rehabilitation comprise education of the blind in special schools and utilization of their services in gainful employment. The central government has established National Institute for the Blind in Dehradun (U.P) to work out new approaches and strategies for solving the problems of the blind.

(d) Specific programmes
(i) Trachoma control: Endemic trachoma and associated infections are a major cause of preventable blindness in many developing countries. Early diagnosis and treatment will cure trachoma. National programmes have been mounted against trachoma in many countries. Mass campaigns with topical tetracycline and the improvement of socio-economic conditions have markedly reduced the severity of trachoma and associated bacterial conjunctival infections. The Trachoma Control Programme launched in India in 1963 was merged with the National Programme for the Control of Blindness in 1976.

(ii) School eye health services: This is another useful approach to the eye health problems in the community. School children who form a sizable segment of the community can be screened and treated for defects such as refraction errors, squint, amblyopia, trachoma, etc. Health education is an important component of school health service. Students should be taught to practise the principles of good posture, proper lighting, avoidance of glare, proper distance and angle between the books and the eyes. Use of suitably readable type style in textbooks should be encouraged.

(iii) Vitamin A prophylaxis: Under the vitamin A distribution scheme in India, 200,000 IU of vitamin A are given orally at 6-monthly intervals between the ages 1–6 years. To be able to control xerophthalmia, the whole family should be kept under surveillance for one year and children for 5 years (16).

(iv) Occupational eye health services: This is to prevent treat eye hazards in industries. Education on the prevention of occupational eye hazards and the use of protective devices in some occupations (like welding) is essential. The key to the prevention of accidents in factories is to improve the safety features of machines, to have proper illumination of the working area, to select workers with the requisite alertness and good vision, and to encourage the use of protective devices (14).

3. LONG-TERM MEASURES
Long-term measures also have a part to play in controlling eye infections. Broadly these measures are aimed at improving the quality of life and modifying or attacking the factors responsible for the persistence of eye health problems, e.g., poor sanitation, lack of adequate safe water supplies, little intake of foods rich in vitamin A, lack of personal hygiene, etc. Health education is an important long-term measure in order to create community awareness of the problem; to motivate the community, to accept total eye health care programmes, and to secure community participation.

4. EVALUATION
Evaluation should be an integral part of intervention programmes to measure the extent to which ocular diseases and blindness have been alleviated, assess the manner and degree to which programme activities have been carried out, and determine the nature of other changes that may have been produced (17).

National and International agencies
The National Association for the Blind (NAB), a voluntary organization which came into existence in 1952 has been active in the field of providing welfare services to the blind throughout India. The Royal Commonwealth Society for the Blind has been working in the field since 1950. In 1974, by invitation of WHO, the organizations concerned with blindness and with its prevention came together to build a new agency, the "International Agency for Prevention of Blindness". The Agency's primary task is to prevent blindness. There is a growing movement for direct technical cooperation among the developing countries. Neighbouring countries may provide training, exchange workers, share plans, and, in a variety of ways enrich and stimulate their programmes (17).

National Programme for the Control of Blindness and Visual Impairment
See chapter 7 for details.

Vision 2020: The Right to Sight
Vision 2020: The Right to Sight, a global initiative to eliminate avoidable blindness was launched by WHO on 18th Feb. 1999. One significant way in which this initiative differs from previous ones is that the concept centres around Rights issues. Recognition of sight as a fundamental human right by all countries can be an important catalyst of initiatives for the prevention and control of blindness. The objective of Vision 2020 is to assist member countries in developing sustainable systems which will enable them to eliminate avoidable blindness from major causes, i.e. cataract, xerophthalmia and other causes of childhood blindness. refractive error and low vision, trachoma and other causes of corneal blindness by the year 2020 (9, 5).

Global eye health action plan 2014–2019 (18)
The global eye health action plan 2014–2019 aims to reduce avoidable visual impairment as a global public health problem and to secure access to rehabilitation services for the visually impaired.

The global eye health action plan is based on five principles and approaches which underpin the plan: universal access and equity, human rights, evidence-based practice, a life course approach, and empowerment of
people with visual impairment. As there have been significant shifts in the pattern of causes of visual impairment, the action plan is structured to particularly address the global trend towards an increasing incidence of chronic eye diseases related to ageing. These are expected to be the most prevalent causes of avoidable visual impairment in the next decades.

The global eye health action plan is built using the health system approach, which encompasses the integration of eye care programmes into the wider health care system at all levels (primary, secondary and tertiary). As a global target, the reduction in prevalence of avoidable visual impairment by 25 per cent by 2019, from the baseline of 2010 has been selected for this action plan.

There are three indicators at the goal and purpose levels to measure progress at the national level: (1) The prevalence and causes of visual impairment; (2) The number of eye care personnel; and (3) Cataract surgery.

Source: (2)

Taking into account the oral health situation in the country, Govt. of India has initiated a National Oral Health Programme during the year 2014-2015, to provide integrated and comprehensive oral health care in the existing health care facilities (3).

RISK FACTORS
Most oral diseases and conditions share modifiable risk factors (such as tobacco use, alcohol consumption and unhealthy diets high in free sugars) common to the four leading NCDs (cardiovascular diseases, cancer, chronic...
respiratory diseases and diabetes). In addition, it is reported that diabetes mellitus is linked in a reciprocal way with the development and progression of periodontitis. Moreover, there is a causal link between high sugars consumption and diabetes, obesity and dental caries.

**Oral Health inequalities:**

Oral health inequalities are caused by a broad range of interacting biological, socio-behavioural, psychosocial, societal and political factors that create "the conditions in which people are born, grow, live, work and age" - the so-called social determinants. Oral diseases disproportionately affect the poor and socially-disadvantaged members of society. There is a very strong and consistent association between socioeconomic status (income, occupation and educational level) and the prevalence and severity of oral diseases. This association exists across the life course from early childhood to older age, and across populations in high, middle and low-income countries. Oral health inequalities are therefore considered as differences in oral health that are avoidable, and deemed both unfair and unjust in modern society (1).

**Oral Diseases (1)**

**Dental caries (tooth decay)**

Dental caries results when microbial biofilm (plaque) formed on the tooth surface converts the free sugars contained in foods and drinks into acids that dissolve tooth enamel and dentine over time. With continued high intake of free sugars, inadequate exposure to fluoride and without regular microbial biofilm removal, tooth structures are destroyed, resulting in development of cavities and pain, impacts on oral-health-related quality of life, and, in the advanced stage, tooth loss and systemic infection.

**Periodontal (gum) disease**

Periodontal disease affects the tissues that both surround and support the tooth. This often presents as bleeding or swollen gums (gingivitis), pain and sometimes as bad breath. In its more severe form, loss of gum attachment to the tooth and supporting bone causes "pockets" and loosening of teeth (periodontitis). Severe periodontal disease, which may result in tooth loss, was the 11th most prevalent disease globally in 2016. The main causes of periodontal disease are poor oral hygiene and tobacco use.

**Tooth loss**

Dental caries and periodontal diseases are major causes of tooth loss. Severe tooth loss and edentulism (no natural teeth remaining) are widespread and particularly seen among older people. Severe tooth loss and edentulism was one of the leading ten causes of years lived with disability (YLD) in some high income countries due to their aging populations.

**Oral cancer**

Oral cancer includes cancers of lip and all subsites of the oral cavity, and oropharynx. The age-adjusted incidence of oral cancer (cancers of the lip and oral cavity) in the world is estimated at 4 cases per 100,000 people. However, there is wide variation across the globe: from no recorded cases to around 20 cases per 100,000 people. Oral cancer is more common in men, in older people, and varies strongly by socio-economic condition. In some Asian-Pacific countries, the incidence of oral cancer ranks among the three top cancers. Tobacco, alcohol and areca nut (betel quid) use are among the leading causes of oral cancer. In regions like North America and Europe, "high risk" human papillomavirus infections are responsible for a growing percentage of oro-pharyngeal cancers among young people.

**Oral manifestations of HIV infection**

Oral manifestations occur in 30–80% of people with HIV, with considerable variations depending on the situations such as affordability of standard antiretroviral therapy (ART). Oral manifestations include fungal, bacterial or viral infections of which oral candidiasis is the most common and often the first symptom early in the course of the disease. Oral HIV lesions cause pain, discomfort, dry mouth, eating restrictions and are a constant source of opportunistic infection. Early detection of HIV-related oral lesions can be used to diagnose HIV infection, monitor the disease's progression, predict immune status and result in timely therapeutic intervention. The treatment and management of oral HIV lesions can considerably improve oral health, quality of life and wellbeing.

**Oro-dental trauma**

Oro-dental trauma is an impact injury to the teeth and/or other hard or soft tissues within and around the mouth and oral cavity. The world prevalence of traumatic dental injuries in either dentition (primary and permanent) is around 20%. Oro-dental trauma can be caused by oral factors (e.g. increased overjet); environmental factors (for example; unsafe playgrounds or schools); risk-taking behaviour; and violence. Treatment is costly and lengthy and sometimes can even lead to tooth loss, resulting in complications for facial and psychological development and quality of life.

**Noma (1)**

Noma is a necrotizing disease that affects children between the ages of 2 and 6 years suffering from malnutrition, affected by infectious disease, living in extreme poverty and with weakened immune systems.

Noma is mostly prevalent in sub-Saharan Africa, but rare cases are reported in Latin America and Asia. Noma starts as a soft tissue lesion (a sore) of the gums, inside the mouth. The initial gum lesion then develops into an ulcerative, necrotizing gingivitis that progresses rapidly, destroying the soft tissues and further progressing to involve the hard tissues and skin of the face.

In 1998, WHO estimated that there were 140,000 new cases of noma annually. Without treatment, noma is fatal in 90% of cases. Where noma is detected at an early stage, its progression can be rapidly halted, through basic hygiene, antibiotics and nutritional rehabilitation. Such early detection helps to prevent suffering, disability and death. Survivors suffer from severe facial disfigurement, have difficulty speaking and eating, face social stigma, and require complex surgery and rehabilitation.

**Cleft lip and cleft palate**

Clefts of the lip and palate are heterogeneous disorders that affect the lips and oral cavity, and occur either alone (70%) or as part of a syndrome, affecting more than 1 in 1000 newborns worldwide. Although genetic predisposition is an important factor for congenital anomalies, other modifiable risk factors such as poor maternal nutrition, tobacco consumption, alcohol and obesity during pregnancy also play
Prevention of oral diseases (1)

The burden of oral diseases can be reduced through public health interventions by addressing common risk factors. These are:

- Promoting a well-balanced diet:
  - Low in free sugars to prevent development of dental caries, premature tooth loss and other diet-related NCDs;
  - With adequate fruit and vegetable intake, which may have a protective role in oral cancer prevention;

- Reducing smoking, the use of smokeless tobacco including chewing of areca nuts, and alcohol consumption to reduce the risk of oral cancers, periodontal disease and tooth loss; and

- Encouraging use of protective equipment in sports and when traveling in motor vehicles, to reduce the risk of facial injuries.

Dental caries can be largely prevented by maintaining a constant low level of fluoride in the oral cavity. Optimal fluoride can be obtained from different sources such as fluoridated drinking water, salt, milk and toothpaste. Twice-daily tooth brushing with fluoride-containing toothpaste (1000 to 1500 ppm) should be encouraged. Long-term exposure to an optimal level of fluoride results in substantially lower incidence and prevalence of tooth decay across all ages.

Oral health inequalities must be reduced by tackling the broader social determinants through a range of complementary downstream, midstream and integrated upstream policies such as: water fluoridation; regulation of the marketing and promotion of sugary foods to children and taxes on sugar-sweetened beverages. Moreover, promoting healthy settings such as healthy workplaces and health promoting schools is critical to building comprehensive supporting environments to promote oral health.

ACCIDENTS AND INJURIES

An accident has been defined as: “an unexpected, unplanned occurrence which may involve injury” (1). A WHO Advisory Group in 1956 defined accident as an “unpremeditated event resulting in recognizable damage” (2). According to another definition, an accident is that “occurrence in a sequence of events which usually produces unintended injury, death or property damage”.

Accidents represent a major epidemic of non-communicable disease in the present century. They are no longer considered accidental. They are part of the price we pay for technological progress.

Accidents have their own natural history and follow the same epidemiological pattern as any other disease – that is, the agent, the host and the environment interacting together to produce injury or damage. They occur more frequently in certain age-groups, at certain times of day and week and at certain localities. Some people are more prone to accidents than others and susceptibility is increased by the effect of alcohol and other drugs as well as physiological state such as fatigue. Lastly, a majority of accidents are preventable.

Measurement of the problem

a. MORTALITY

The following epidemiological indices will be useful in assessing the magnitude of the problem; (i) Proportional mortality rate: That is, the number of deaths due to accidents per 100 (or 1000) total deaths. (ii) Number of deaths per million population: The term “killed” (in a road traffic accident) is defined as any person who was killed outright or who died within 30 days as a result of the accident (3). (iii) Death rate per 1000 (or 100,000) registered vehicles per year. (iv) Number of accidents or fatalities as a ratio of the number of vehicles per kilometre or passengers per kilometre. (v) Deaths of vehicle occupants per 1000 vehicles per year, etc.

b. MORBIDITY

Morbidity is measured in terms of “serious injuries” and “slight injuries” (4). The seriousness of the injury is assessed by a scale known as “Abbreviated Injury Scale” (3). Morbidity rates are generally less reliable because of under-reporting and mis-reporting.

c. DISABILITY

An important outcome of the accident process is disability, which may be temporary or permanent, partial or total. Measurement of disability in terms of its duration is a limited concept; it does not take into consideration the psychological or social aspects of an accident or injury (5). The International classification of “Functioning, Disability and Health” (ICF) is an attempt by WHO (6) to estimate the disability of individuals at a given moment.

The problem

WORLD

Injuries constitute a variable epidemic. Injuries are commonly classified based on “intentionality”. Most road traffic injuries, poisoning, falls, fire and burn injuries and drowning are unintentional. Intentional injuries include interpersonal violence (homicide, sexual assault, neglect and abandonment, and other maltreatment), suicide and collective violence (war). Evidence suggests that some children and adolescents are more vulnerable to certain types of injuries. For example poisoning, drowning, burns and maltreatment by caregivers affects primarily small children, while road traffic accidents, interpersonal violence and sports injuries tend to affect older children, adolescents and adults (7).

The leading cause of injury deaths is road traffic injury, followed by suicide, falls and interpersonal violence. Other important cause of injuries include drowning, fires and burns, poisoning, and war or conflict (1). Table 1 shows the global estimated deaths by type of injury, percentage of total deaths, crude death rate per lakh population and age specific death rate per lakh population due to injuries during the year 2016 (8).

### INDIA

Accidents are definitely on an increase in India. Increasing mechanization in agriculture and industry, induction of semi-skilled and unskilled workers in various operations and rapid increase in vehicular traffic have resulted in an increase in morbidity and mortality due to accidents. Overcrowding, lack of awareness and poor implementation of essential safety precautions result in an increasing number of accidents. Consumption of poisonous substances accidentally or intentionally is also on the rise. Deaths, disabilities and hospitalization due to injuries continue to have impact of socio-economic loss to individuals, families, society and infrastructure. The traditional view of injury as an accident, has resulted in the neglect of this aspect of public health. Today injuries are low in priority for policy makers, and only few plans are drawn for injury prevention.

Table 3 shows the reported number of accidental deaths by main causes in India.

### TYPES OF ACCIDENTS

1. **Road traffic accidents**

In many countries, motor vehicle accidents rank first among all fatal accidents. Every year almost 1.25 million people die from road accidents in the world. In addition, for every death, there are as many as 20–50 non-fatal injuries and 10–20 serious injuries requiring long periods of
enforcing sobriety check-points and random breath tests. The risk of being involved in a crash increases if the driver has a blood alcohol concentration (BAC) above 0.04 g/dl. Laws that establish BACs of 0.05 g/dl or below are more effective at reducing the number of alcohol-related crashes. Enforcing sobriety check-points and random breath testing can lead to reductions in alcohol-related crashes by about 20%, and have shown to be very cost-effective.

Apart from reducing road traffic injuries, lower average speeds can reduce the risk of a crash and the consequences of the crash. Some other differences are as below:

**Motorcycle helmets**
- Wearing a motorcycle helmet correctly can reduce the risk of death by almost 40% and the risk of severe injury by over 70%.
- When motorcycle helmet laws are enforced effectively, helmet wearing rates can increase to over 90%.
- Requiring helmets to meet a recognized safety standard is important to ensure that helmets can effectively reduce the impact of a collision to the head in the event of a crash.

**Seat-belts and child restraints**
- Wearing car seat-belts reduces the risk of fatality among front-seat passengers by 40-50% and of rear-seat passengers by between 25-75%.
- Mandatory seat-belt laws and their enforcement have been shown to be very effective at increasing seat-belt wearing rates.
- If correctly installed and used, child restraints reduce deaths among infants by approximately 70%, and deaths among small children by between 54% and 80%.

**Distracted driving**
There are many types of distractions that can lead to impaired driving, but recently there has been a marked increase around the world in the use of mobile phones by drivers that is becoming a growing concern for road safety. The distraction caused by mobile phones can impair driving performance in a number of ways, e.g. longer reaction times (notably braking reaction time), but also reaction to traffic signals, impaired ability to keep in the correct lane, and shorter following distances.
- Text messaging also results in considerably reduced driving performance, with young drivers at particular risk of the effects of distraction resulting from this use.
- Drivers using a mobile phone are approximately four times more likely to be involved in a crash than when a driver does not use a phone. Hands-free phones are not much safer than hand-held phone sets.
- While there is little concrete evidence yet on how to reduce mobile phone use while driving, governments need to be proactive. Actions that can be taken include adopting legislative measures, launching public awareness campaigns, and regularly collecting data on distracted driving to better understand the nature of this problem.

Developing countries are very different from the industrialized countries with regard to the environment and the mix of vehicles in the traffic stream. The following are the more important differences (13):

1. Large numbers of pedestrians and animals share the roadway with fast-moving and slow-moving (e.g., bullock carts) vehicles. There is almost no segregation of pedestrians from wheeled traffic;
2. Large numbers of old, poorly maintained vehicles;
3. Large numbers of motor cycles, scooters, and mopeds;
4. Low driving standards;
5. Large numbers of buses, often overloaded;
6. Widespread disregard of traffic rules;
7. Defective roads, poor street lighting, defective lay-out of cross roads and speed breakers; and
8. Unusual behaviour of men and animals.
In South-East Asia Region countries, semi-urban and rural areas contribute 60-80 per cent of road accident injuries, although all media attention is focussed on urban road accidents.

Road traffic injuries cause the considerable economic loss to victims, their families, and to the nation as a whole. These losses arise from the cost of treatment (including rehabilitation and incident investigation) as well as reduced lost productivity (e.g. in wages) for those killed or disabled by their injuries, and for family members who need to take time off work (or school) to care for the injured (11).

Multiple causation

Accidents are a complex phenomena of multiple causation (Fig. 1). The aetiological factors may be classified into two broad categories - human and environmental. Upto 90 per cent of the factors responsible for accidents are attributed to human failure. Many of the psychological circumstances in which accidents occur are still poorly known (5).

PREVENTION

Accidents don't just happen; they are caused. The causes in a given situation must be identified by epidemiological methods. Since accidents are multifactorial, they call for an intersectoral approach to both prevention and care of the injured. The various measures comprise the following:

1. Data collection

There should be a basic reporting system of all accidents. The national data should be supplemented by special surveys and in-depth studies. These studies will bring out the risk factors, the circumstances and chain of events leading
upto the accident. These details are rarely provided by the basic reporting system. Detailed environmental data relating to the road, vehicle, weather, etc must also be collected. The police have a statutory duty in many countries to investigate accidents, for legal as well as preventive purposes: the data collecting systems should recognize this and take police records as their starting point (3). Without adequate data collection, analysis and interpretation there could be no effective counter-measures, evaluations and strategies for prevention.

2. Safety education

There is a widespread belief that accidents are inevitable: this fatalistic attitude must be curbed. Safety education must begin with school children. The drivers need to be trained in proper maintenance of vehicles and safe driving. Young people need to be educated regarding risk factors, traffic rules and safety precautions. They should also be trained in first aid. It has been aptly said that “if accident is a disease, education is its vaccine”.

3. Promotion of safety measures

(a) Seat belts: The use of seat belts reduces the number of fatalities and non-fatal injuries by approximately 50 per cent each. They should be made compulsory for cars, light trucks and similar vehicles (3). (b) Safety helmets: They reduce the risk of head injury by 30 per cent on an average and that of fatalities by 40 per cent (5). They prevent laceration of the scalp to a great extent. Recently, the full-face integral helmet has become very popular. (c) Children: Another safety measure is to ensure that children remain seated when they are in a vehicle. They should be prohibited to take the front seats of cars (5). A few countries have introduced laws which require that children of under 12–15 years in cars to be in the rear seats only. (d) Others: These comprise use of door locks, proper vehicle design, use of laminated high-penetration resistance windscreen glass, etc.

4. Alcohol and other drugs

Alcohol impairs driving ability and increases the risk of an accident as well as the severity of its consequences. Conclusions of surveys carried out in several countries have shown that alcohol is the direct cause of 30 to 50 per cent of severe road accidents.

Drugs such as barbiturates, amphetamines, and cannabis impair one’s ability to drive safely. They should be avoided totally.

5. Primary care

Planning, organization and management of trauma treatment, and emergency care services should be a fundamental element of health service managerial process. Emergency care should begin at the accident site, continued during transportation, and conclude in the hospital emergency room. At any of these stages a life may be saved or lost, depending upon the skill of the health care worker and the availability of needed emergency equipment. To achieve these ends, there should be an Accident Services Organization and one fully equipped specialized trauma care hospital in all major cities.

6. Elimination of causative factors

The factors which tend to cause accidents must be sought out and eliminated, e.g., improvement of roads, imposition of speed limits and marking of danger points.

7. Enforcement of laws

Legislation embodies codified set of rules. These are enforced by the State to prevent accidents. These include driving tests, medical fitness to drive, enforcement of speed limits, compulsory wearing of seat-belts and crash-helmets, checking of blood alcohol concentration, road-side breath testing for alcohol, regular inspection of vehicles, periodic re-examination of drivers over the age of 55, etc.

8. Rehabilitation services

Rehabilitation consists of a number of elements which each injured person should benefit from. These are medical rehabilitation, social rehabilitation, occupational rehabilitation, etc. The aim of rehabilitation is to prevent, reduce or compensate disability and thereby handicap.

9. Accident research

The future of accident prevention is in research. Such research will be concerned with gathering precise information about the extent, type and other characteristics of accidents, correlating accident experience with personal attributes and the environments in which accidents occur, investigating new and better methods of altering human behaviour; seeking ways to make environments safer; and evaluating more precisely the efficiency of control measures. This area is now termed accidentology.

2. Domestic accidents

By “domestic accident” is meant an accident which takes place in the home or in its immediate surroundings, and, more generally, all accidents not connected with traffic, vehicles or sport (14). The most frequent causes of domestic accidents are:

1. drowning;
2. burns (by a flame, hot liquid, electricity, crackers or fire works, chemicals);
3. falls;
4. poisoning (e.g., drugs, insecticides, rat poisons, kerosene);
5. injuries from sharp or pointed instruments; and
6. bites and other injuries from animals

**Drowning (15)**

Drowning is the process of experiencing respiratory impairment from submersion/immersion in liquid.

Victims of drowning have a very slim chance of survival after immersion. The victim loses consciousness after approximately 2 minutes of immersion, and irreversible brain damage can take place after 4–6 minutes. Therefore, prevention strategies are very important.

In 2016, an estimated 322,000 people died from drowning, making drowning a major public health problem worldwide. Injuries account for nearly 9% of total global mortality. Drowning is the 3rd leading cause of unintentional injury/death. It accounts for 7% of all injury-related deaths. It is a common method of suicide (16).

The global burden and death from drowning is found in all economies and regions; however, low and middle-income countries account for 90% of unintentional drowning deaths; over 50% of the world’s drowning occurs in the WHO Western Pacific Region and WHO South-East Asia Region; China and India have particularly high drowning mortality rates and together contribute 43% of the world’s drowning deaths and 41% of the total global DALYS (disability-adjusted life years) lost related to drowning.
There is a wide range of uncertainty around the estimate of global drowning deaths. It is important to point out that the global problem is much greater than the above figures reveal; due to the way data are classified, global numbers exclude drowning due to floods (cataclysms), boating and water transport mishaps. Non-fatal drowning statistics in many countries are not readily available or are unreliable.

Risk factors (15)

1. **Age** : Age is one of the major risk factor for drowning. This relationship is often associated with a lapse in supervision. In general, children under 5 years of age have the highest drowning mortality rates worldwide. Canada and New Zealand are the only exceptions, where adult males drown at higher rates.

2. **Gender** : Males are especially at risk of drowning with twice the overall mortality rate of females. They are more likely to be hospitalized than females for non-fatal drowning. Studies suggest that the higher drowning rates among males are due to increased exposure to water and riskier behaviour such as swimming alone, drinking alcohol before swimming alone, and boating.

3. **Access to water** : Increased access to water is another risk factor for drowning. Individuals with occupations such as commercial fishing or fishing for subsistence, using small boats in low-income countries, are more prone to drowning. Children who live near open water sources, such as ditches, ponds, irrigation channels, or pools are especially at risk.

4. **Other risk factors** : There are other factors that are associated with an increased risk of drowning, such as:
   - infants left unsupervised or alone, or with another child in a bathtub;
   - unsafe or overcrowded transportation vessels lacking flotation devices;
   - alcohol use, near or in the water;
   - medical conditions, such as epilepsy;
   - tourists unfamiliar with local water risks and features; and
   - floods and other cataclysmic events like tsunamis.

Prevention (15)

Drowning prevention strategies should be comprehensive and include: engineering methods which help to remove the hazard, legislation to enforce prevention and assure decreased exposure, education for individuals and communities to build awareness of risk and to aid in response if a drowning occurs.

Engineering methods to eliminate exposure to water hazards are the most effective strategy for drowning prevention. Examples include:

- development and implementation of safe water systems, such as drainage systems, piped water systems, flood control embankments in flood prone areas;
- building four-sided pool fences or barriers preventing access to standing water;
- creating and maintaining safe water zones for recreation;
- covering of wells or open cisterns;
- emptying buckets and baths, and storing them upside-down.

Laws or regulations which target risk factors for drowning include laws requiring regular safety checks of transportation vessels, and laws on alcohol use while boating or swimming.

Individual and community education on drowning awareness, learning water survival skills and ensuring the presence of lifeguards at swimming areas are promising strategy to prevent drowning.

Burns (17)

A burn is an injury to the skin or other organic tissue primarily caused by heat or due to radiation, radioactivity, electricity, friction or contact with chemicals. Thermal (heat) burns occur when some or all of the cells in the skin or other tissues are destroyed by:

- hot liquids (scalds);
- hot solids (contact burns), or
- flames (flame burns).

The problem

Burns are a global public health problem, accounting for an estimated 180,000 deaths annually. About 11 million people worldwide require medical attention due to severe burns. The majority of these occur in low and middle-income countries and almost half occur in the South-East Asia Region.

In many high-income countries, burn death rates have been decreasing, and the rate of child deaths from burns is currently over seven times higher in low and middle-income countries than in high-income countries.

Non-fatal burns are a leading cause of morbidity, including prolonged hospitalization, disfigurement and disability, often with resulting stigma and rejection. It is estimated that over one million people are moderately or severely burnt every year in India. In Bangladesh 1.73 lac children get moderate or severe burns every year with about 17 per cent getting temporary disability and 18 per cent permanent disability. Burns are the second most common injury in rural Nepal accounting for 5 per cent disabilities.

Risk factors (17)

**Gender** : Females suffer burns more frequently than males. Women in the South-East Asia Region have the highest rate of burns, accounting for 27% of global burn deaths and nearly 70% of burn deaths in the region. The high risk for females is associated with open fire cooking, or inherently unsafe cookstoves, which can ignite loose clothing. Open flames used for heating and lighting also pose risks, and self-directed or interpersonal violence are also important factors (although understudied).

**Age** : Along with adult women, children are particularly vulnerable to burns. Burns are the 11th leading cause of death of children aged 1–9 years and are also the fifth most common cause of non-fatal childhood injuries. While a major risk is improper adult supervision, a considerable number of burn injuries in children result from child maltreatment.

Socio-economic factors

People living in low and middle-income countries are at higher risk for burns than people living in high-income countries. Within the countries also, burn risk correlates with socio-economic status.
Other risk factors

There are a number of other risk factors for burns, including:

- occupations that increase exposure to fire;
- poverty, overcrowding and lack of proper safety measures;
- placement of young girls in household roles such as cooking and care of small children;
- underlying medical conditions, including epilepsy, peripheral neuropathy, and physical and cognitive disabilities;
- alcohol abuse and smoking;
- easy access to chemicals used for assault (such as in acid violence attacks);
- use of kerosene (paraffin) as a fuel source for non-electric domestic appliances;
- inadequate safety measures for liquefied petroleum gas and electricity.

Burns occur mainly in the home and workplace. Community surveys in Bangladesh and Ethiopia showed that 80–90% of burns occur at home. Children and women usually get burns in domestic kitchens, from upset receptacles containing hot liquids, or flames, or from cookstove explosions. Men are more likely to get burns in the workplace due to fire, scalds, chemicals and electricity.

Prevention (17)

Burns are preventable. High-income countries have made considerable progress in lowering rates of burn deaths, through a combination of prevention strategies and improvements in the care of people affected by burns. Most of these advances in prevention and care have been incompletely applied in low and middle-income countries. Increased efforts to do so would likely lead to a significant reduction in rates of burn-related death and disability.

Prevention strategies should address the hazards for specific burn injuries, education for vulnerable populations and training of communities in first-aid. An effective burn prevention plan should be multisectoral. There are a number of specific recommendations for individuals, communities and public health officials to reduce burn risk.

FIRST-AID (17)

Do's

1. Stop the burning process by removing clothing and irrigating the burns.
2. Use cool running water to reduce the temperature of the burn.
3. Extinguish flames by allowing the person to roll on the ground, or by applying a blanket, or by using water or other fire-extinguishing liquids.
4. In chemical burns, remove or dilute the chemical agent by irrigating with large volumes of water.
5. Wrap the patient in a clean cloth or sheet and transport to the nearest appropriate facility for medical care.

Don'ts

1. Do not start first-aid before ensuring your own safety (switch off electrical current, wear gloves for chemicals etc.)
2. Do not apply paste, oil, haldi (turmeric) or raw cotton to the burn.
3. Do not apply ice because it deepens the injury.
4. Avoid prolonged cooling with water because it may lead to hypothermia.
5. Do not open blisters until topical antimicrobials can be applied, by a healthcare provider.
6. Do not apply any material directly to the wound as it might become infected.
7. Avoid application of topical medication until the patient has been placed under appropriate medical care.

Falls

Globally, falls are a major public health problem. An estimated 646,000 fatal falls occur each year, making it the second leading cause of unintentional injury death, after road traffic injuries. Though not fatal 37.3 million falls are severe enough to require medical attention. Such falls are responsible for 17 million DALY's lost. Over 80% of fall-related fatalities occur in low and middle-income countries, with regions of the Western Pacific and South East Asia accounting for more than two-thirds of these deaths. In all regions of the world, death rates are highest among adults over the age of 65 years (18).

Falls are responsible for the largest number of hospital visits for non-fatal injuries, especially for children and young adults. Falls from rooftops, balconies, windows and stair cases are common. Factors specific to SEAR countries are falls from trees of workers picking fruits or coconuts, tapping toddy, children falling from rooftops while flying kites, high incidence of falls among construction and forestry workers. As life expectancy increases in these countries, the incidence of hip and other fractures due to fall among the elderly are also assuming greater proportions (19).

Some of the risk factors include (18):

- occupations at elevated heights or other hazardous working conditions;
- alcohol or substance use;
- socio-economic factors including poverty, overcrowded housing, young maternal age;
- underlying medical conditions, such as neurological, cardiac or other disabling conditions;
- side-effects of medication, physical inactivity and loss of balance, particularly among older people;
- unsafe environments, particularly for those with poor balance and limited vision.

Prevention (18)

For children, effective interventions include multifaceted community programmes; engineering modifications of nursery furniture, playground equipment, and other products; and legislation for the use of window guard.

For older individuals, fall prevention programmes can include a number of components to identify and modify risk, such as:

- screening within living environments for risks for falls;
- clinical interventions to identify risk factors, such as medication review and modification, treatment of low blood pressure, Vitamin D and calcium supplementation, treatment of correctable visual impairment;
- home assessment and environmental modification for those with known risk factors or a history of falling;
— prescription of appropriate assistive devices to address physical and sensory impairments;  
— muscle strengthening and balance retraining prescribed by a trained health professional;

Poisoning

Poisoning was responsible for an estimated 252,000 deaths during the year 2008 worldwide. In India about 28,012 poisoning deaths were reported during the year 2010 (20). The most common agents responsible for poisoning are pesticides, kerosene, prescription drugs, and household chemicals. Pesticides are widely used in many countries where agriculture is a significant part of the economy. Reports from India, Indonesia, Sri Lanka, and Thailand indicate that common availability and use of toxic pesticides is responsible for intentional and unintentional morbidity and mortality.

In Sri Lanka, pesticides are one of the main agents used in attempted suicide in rural areas. The use of organophosphorous insecticides in suicide events has been reported to be as high as 20–30 per cent. Paraquat intoxication is known to cause irreversible damage in patients. Many countries also report accidental ingestion of kerosene as a leading cause of poisoning, especially among children (19). A study from Thailand revealed that 54 per cent of cases of poisoning among pre-school children involved therapeutic drugs.

Snake bite

Snake bite is a neglected public health issue in many tropical and subtropical countries. About 5.4 million snake bites occur each year, resulting in up to 2.7 million envenomations (poisoning from snake bites) at least 81,000–138,000 deaths and around 3 times amputations and other permanent disabilities. Most of these occur in Africa, Asia, and Latin America. In Africa alone there are an estimated 1 million snake bites annually with about half needing treatment. This type of injury is often found among women, children, and farmers in poor rural communities in low- and middle-income countries (21).

The outcome of snake bite depends on numerous factors, including the species of snake, the area of the body bitten, the amount of venom injected, and the health condition of the victim. Feelings of terror and panic are common after a snake bite and can produce a characteristic set of symptoms mediated by the autonomic nervous system, such as tachycardia and nausea. Bites from non-venomous snakes can also cause injury, often due to lacerations caused by the snake's teeth, or from a resulting infection. A bite may also trigger an anaphylactic reaction, which is potentially fatal.

First-aid recommendations for bite depend on the snake's species. The venom of poisonous snakes may be predominantly neurotoxic or predominantly cytolytic. Neurotoxins cause respiratory paralysis and cytolytic venoms cause tissue destruction by digestion and haemorrhage due to haemolysis and destruction of the endothelial lining of the blood vessels. The manifestations of rattlesnake envenomation are mostly local pain, redness, swelling and extravasation of blood. Perioral tingling, metallic taste, nausea, and vomiting, hypotension and coagulopathy may also occur. Neurotoxic envenomation may cause ptosis, dysphagia, diplopia, and respiratory failure. Venom emitted from some types of cobras, almost all vipers cause necrosis of muscle tissue. Muscle tissues begin to die throughout the body and it results in accumulation of myoglobin in the renal tubules which leads to acute renal failure.

Early clues that a patient has severe envenoming (22):

1. Snake identified as a very dangerous one;
2. Rapid early extension of local swelling from the site of the bite;
3. Early tender enlargement of local lymph nodes, indicating spread of venom in the lymphatic system;
4. Early systemic symptoms: collapse (hypotension, shock), nausea, vomiting, diarrhoea, severe headache, “heaviness” of the eyelids, inappropriate (pathological) drowsiness or early ophthamoplegia;
5. Early spontaneous systemic bleeding;
6. Passage of dark brown/black urine.

FIRST-AID

The Government of India developed a national snake-bite protocol in 2007 which includes following advice:

1. Reassure the patient. 70% of all snake bites are from non-venomous species. Only 50% of bites by venomous species actually envenomate the patient.
2. Immobilize in the same way as a fractured limb. Use bandages or cloth to hold the splints, not to block the blood supply or apply pressure. Do not apply any compression in the form of tight ligatures, they don't work and can be dangerous.
3. Do not give alcoholic beverages or stimulants. They are known vasodilators and they speed up the absorption of venom;
4. Remove any items or clothing which may constrict the bitten site. Do not apply compression in the form of tight ligatures, they don't work and can be dangerous;
5. Do not incise or manipulate the bitten site. Do not apply ice; and
6. Transport the patient to a medical facility for definitive treatment

ANTIVENOM (22)

Until the advent of antivenom, bites from some species of snake were almost universally fatal. Despite huge advances in emergency therapy, antivenom is often still the only effective treatment for envenoming. The first antivenom was developed in 1895 by French physician Albert Calmette for the treatment of Indian cobra bites. Antivenom is made by injecting a small amount of venom into an animal (usually a horse or sheep) to initiate an immune system response. The resulting antibodies are then harvested from the animal's blood.

Antivenom is injected into the person intravenously, and works by binding to, and neutralizing venom enzymes. It cannot undo damage already caused by venom, so antivenom treatment should be sought as soon as possible. Modern antivenoms are usually polyvalent, making them effective against the venom of numerous snake species.

Pharmaceutical companies which produce antivenom target their products against the species native to a particular area. Although some people may develop serious adverse reactions to antivenom, such as anaphylaxis, in emergency situations this is usually treatable and hence the
benefit outweighs the potential consequences of not using antivenom.

3. Industrial accidents

There are approximately 580 million workers in the South-East Asia Region. Approximately 60–80 per cent of these workers are employed in agriculture, fisheries, home industries, and small-scale units. Injuries due to these occupations result in an estimated 120 million injuries and 200,000 deaths per year (19).

Though reliable estimates for work related injuries and deaths in the Region are not available, partly because a majority of the workers are employed in unorganized sectors, few studies indicate that nearly one per cent of deaths and 10 per cent of permanent impairment result from agricultural injuries. Agriculture workers are exposed to a wide variety of physical, chemical (pesticide and fertilizers), biological (animal bites and animal related injuries) and mechanical injuries. The estimates from agriculture injury vary from 22–29 per 1000 workers. The incidence rate of injury among agriculture workers in India is estimated to be 116 per 100,000 workers. In a study population of 23,000 in rural Haryana, nearly 31 per cent of the injuries were related to agricultural activity (23). Of these, serious injuries were caused by mechanized equipment and tractors (19).

Rapid industrialization has also resulted in mortality and morbidity of many workers in hazardous industries.

The unique features common to the workplace in this region are that the manual labour content is high and the man–machine interaction is unsafe. In addition, there is greater emphasis on attempts to change the worker’s behaviour, but designs that provide automatic protection are ignored. Children and people who are challenged physically as well as mentally are at a greater risk of encountering occupational injuries (19).

4. Railway accidents

With the increase in number of trains and passengers, the increase in the number of accidents and casualties resulting therefrom is not unexpected. During 2010, about 30,576 people died of railway accidents in India (9). The main factor involved in railway accidents is human failure.

5. Violence

Homicide and collective violence account for around 10% of global, injury-related death. In 2016, there were an estimated 477,000 murders. Four fifths of homicide victims are men, and 60% of victims, males age 15–44. The lowest and middle-income countries of the Region of the Americas has the most homicides, with 28.5 per 100,000 population, while the lowest murder rate, almost 14 times lower (2.1 per 100,000 population), is found in the low- and middle-income countries of The Western Pacific Region (24).

Violence is reported to be increasing rapidly. It also follows the same epidemiological pattern as any other disease (host, agent and environment), i.e. a motivated person who injures; a suitable target; and a suitable environment or the absence of a guardian, all coinciding in time and space. Often, it may only be possible to initiate steps for prevention after an episode of violence has already taken place.

Some of the risk factors for violent behaviour are (19):

- Exposure to violence and societal acceptability of violence as a means to solve problems. The image of violence as an acceptable and effective tool for solving problems, whether across international borders, on the street, or around the home, may spill over into real behaviour;
- Availability of lethal weapons like fire-arms significantly increases the possibility of both fatal and non-fatal injuries;
- Consumption of alcohol and other drugs is linked to almost 2/3 of cases of violence according to several studies.

Violence due to war and political unrest is fairly common in several countries. Organized and unorganized, ethnic and communal violence are well known in some places.

Suicides have been increasing at an alarming rate in SEAR countries. Crude death rates of 8.7 per lac population in Bangladesh, 14.7 per lac population in India, 6.4 per lac in Sri Lanka, and 5.9 per lac in Thailand; per year have been reported in 2016 (8).

Nearly 70 per cent of suicides in all countries have been reported in the age group of 15–34 years with male-female ratio of 1:1.2 to 1:3 from different countries. Poisoning, hanging, self-immolation and drowning are the most commonly reported methods of suicide (23).

In India, an average of 369 suicides take place every day, out of these 248 are committed by males and 121 by females (62 are house wives). Family problems (89) and illness (72) are the main cause of suicides. Majority cases are below 29 years of age (136) followed by 30–44 years of age group (125) (12).

References

7. WHO, Children’s Environmental Health, Injuries
Since India became independent, several measures have been undertaken by the National Government to improve the health of the people. Prominent among these measures are the NATIONAL HEALTH PROGRAMMES, which have been launched by the Central Government for the control eradication of the communicable diseases, improvement of environmental sanitation, raising the standard of nutrition, control of population and improving rural health. Various International agencies like WHO, UNICEF, UNFPA, World Bank, as also a number of foreign agencies like SIDA, DANIDA, NORAD and USAID have been providing technical and material assistance in the implementation of these programmes. A brief account of these programmes which are currently in operation is given below:

NATIONAL VECTOR BORNE DISEASE CONTROL PROGRAMME

The National Vector Borne Disease Control Programme (NVBDCP) is implemented in the State/UT’s for prevention and control of vector borne diseases namely Malaria, Filariasis, Kala-azar, Japanese Encephalitis (JE), Dengue and Chikungunya. The Directorate of NVBDCP is the nodal agency for planning, policy making and technical guidance and monitoring and evaluation of programme implementation in respect of prevention and control of these vector borne diseases under the overall umbrella of NRHM. The States are responsible for planning, implementation and supervision of the programme. The vector borne diseases are major public health problems in India. Chikungunya fever which has re-emerged as epidemic outbreaks after more than three decades has added to the problem. The prevention and control of vector borne diseases is complex; as their transmission depends on interaction of numerous ecological, biological, social and economic factors including migration (1).

Out of the six vector borne diseases, malaria, filariasis, Japanese encephalitis, dengue and chikungunya are transmitted by different kind of vector mosquitoes, while kala-azar is transmitted by sand flies. The transmission of vector borne diseases in any area is dependent on frequency of man-vector contact, which is further, influenced by various factors including vector density, biting time, etc. Mosquito density is directly related with water collection, clean or polluted, in which the mosquitoes breed.

Under NVBDCP, the three pronged strategy for prevention and control of VBDs is as follows: (i) Disease management including early case detection and complete treatment, strengthening of referral services, epidemic preparedness and rapid response; (ii) Integrated vector management (IVM) for transmission risk reduction including indoor residual spraying in selected high-risk areas, use of insecticide treated bed-nets, use of larvivorous fish, anti-larval measures in urban areas, source reduction and minor environmental engineering; and (iii) Supportive interventions including behaviour change communication (BCC), public private partnership and inter-sectoral convergence, human resource development through capacity building, operational research including studies on drug resistance and insecticide susceptibility, monitoring and evaluation through periodic reviews, field visits, web based management information system, vaccination against JE and annual mass drug administration against lymphatic filariasis (1).

(A) MALARIA

The programme began originally as National Malaria Control Programme in 1953, during the First Five Year Plan. Because of the spectacular success achieved in the control of malaria, the control programme, was converted in 1958 into an eradication programme, with the objective of eradicating malaria once and for all from the country. Since then the programme has undergone many changes and the milestones of malaria control activities in India are as shown below (2):

Milestones of malaria control activities in India

<table>

</tbody>
</table>
The main activities of the programme are:

1. Formulating policies and guidelines.
2. Technical guidance.
3. Planning.
4. Logistics.
5. Monitoring and evaluation.
6. Coordination of activities through the States/Union Territories and in consultation with national organizations such as National Centre for Disease Control (NCDC), National Institute of Malaria Research (NIMR).
7. Collaboration with international organizations like the WHO, World Bank, GFAFM and other donor agencies.
8. Training.
9. Facilitating research through NCDC, NIMR, Regional Medical Research Centres etc.
10. Coordinating control activities in the inter-state and inter-country border areas.

Organization (2)

There are 19 Regional Offices for Health and Family Welfare under Directorate General of Health Services, Ministry of Health and Family Welfare, located in 19 states, which play a crucial role in monitoring the activities under NVBDCP. These offices are equipped with malaria trained staff.

The state governments are required to plan and implement the malaria control operations in their respective states. Every state has a Vector Borne Disease Control Division under its Department of Health and Family Welfare. It is headed by the State Programme Officer (SPO) who is responsible for supervision, guidance and effective implementation of the programme and coordination of the activities with the neighboring States/UTs. States are responsible for the procurement of certain insecticides for indoor residual spraying (IRS), spray equipment, and certain antimalarial drugs. The central government supplies DDT and larvicides.

Each state has established a State Vector Borne Disease Control Society, which includes civil society and sometimes private sector representation. These are now merged with similar entities for other centrally-sponsered schemes into a single state-level Health and Family Welfare Society. The main role of these societies is to channelize funds from GOI to the states and onwards to districts for financing of the programmes. They also play a role in district level planning and in monitoring of programme activities within districts.

At the divisional level, zonal officers have technical and administrative responsibilities of the programme in their areas under the overall supervision of Senior Divisional Officers (SDOs).

At the district level, the Chief Medical Officer (CMO)/District Health Officer (DHO) has the overall responsibility of the programme. At the district level, district malaria officers have been established in many places headed by the DVBDPC officer to assist the CMO/DHO. This office is the key unit for the planning and monitoring of the programme. Spray operations are the direct responsibility of DM/DVBDPC officer in the entire union district under overall supervision of CMO and collaborative supervision/monitoring by PHC's Medical Officer. There is one Assistant Malaria Officer (AMO) and Malaria Inspectors (MIs) to assist him (2).

In many districts, District Vector Borne Disease Control Societies (now merged with District Health Societies under NRHM) have been established to assist the management of funds and planning, and monitoring of programme activities.

The laboratories have been decentralized and positioned at the PHCs. The medical officer - PHC has the overall responsibility for surveillance and laboratory services, and also supervises the spray. Case detection management and community outreach services are carried out by MPWs as well as ASHAs and other community health volunteers.

**DRUG DISTRIBUTION CENTRES AND FEVER TREATMENT DEPOTS**

With the increasing number of malaria cases, the demand for antimalarial drugs has increased tremendously. It became clear that drug supply only through the surveillance workers and medical institutions was not enough. This led to the establishment of a wide network of Drug Distribution Centres and Fever Treatment Centres. Drug Distribution Centres are only to dispense the antimalarial tablets as per NMEP schedules. Fever Treatment Depots collect the blood slides in addition to the distribution of antimalarial tablets. These centres are manned by voluntary workers from the community.

**URBAN MALARIA SCHEME**

The urban malaria scheme was launched in 1971 to reduce or interrupt malaria transmission in towns and cities. The methodology comprises vector control by intensive larvicidal measures and drug treatment. About 7.4 per cent of the total cases of malaria and 10.9 per cent of deaths due to malaria are reported from urban areas. Maximum cases are reported from Chennai, Vadodara, Vishakhapatnam, Ahmedabad, Kolkata, New Mumbai, Vijayawada etc. (3). The vector of malaria in the urban areas breeds largely in man-made containers including overhead tanks and underground water storage tanks, water coolers, cisterns, roof gutters, flower vases, bottles and ornamental ponds, old tyres etc., which can collect water. Large construction activities provide suitable breeding sites for the mosquitoes. Influx of migrant labour, from malarious zones contribute to increase in incidence. Control of urban malaria lies primarily in the implementation of civil bye-laws to prevent mosquito breeding in the domestic and peridomestic areas. Use of larvicides in the water bodies such as slow moving streams, ornamental ponds etc is recommended. Larvicides are used for water bodies which are unsuitable for fish use (2). The urban malaria scheme under national vector disease control programme is presently protecting 130 million population from malaria and other mosquito borne diseases in 131 towns in 19 states and Union Territories. The civic bye-laws have been enacted and implemented in Delhi, Mumbai, Kolkata, Chandigarh, Bangalore, Chennai, Ahmedabad and Goa etc (3).

The Expert Committee on Malaria had recommended the inclusion of all urban areas with more than 50,000 population and reporting slide positivity rate of 5 per cent.
and above, under Urban Malaria Scheme and introduction of active surveillance under this scheme.

**National Framework for Malaria Elimination in India (2016–2030)**

Encouraged by the success achieved in malaria control in recent years, the vision of India's malaria control programme has been now shifted to sustained malaria elimination to contribute more effectively to improved health and quality of life of the people. The National Framework for malaria elimination in India 2016–2030 was launched in February 2016.

**Goals**

In line with the WHO Global Technical Strategy (GTS) for Malaria 2016-2030 and the Asia Pacific Leaders Malaria Alliance Malaria Elimination Roadmap, the goals of the National Framework for Malaria Elimination in India 2016–2030 are:

- Eliminate malaria (zero Indigenous cases) throughout the entire country by 2030; and
- Maintain malaria-free status in areas where malaria transmission has been interrupted and prevent re-introduction of malaria.

**Objectives**

The National Framework for Malaria Elimination in India has formulated the following objectives:

- **By 2022**, transmission of malaria interrupted and zero indigenous cases to be attained in all 26 States/UTs that were under Categories 1 and 2 in 2014.
- **By 2024**, incidence of malaria to be reduced to less than 1 case per 1000 population in all States and UTs and their districts.
- **By 2027**, indigenous transmission of malaria to be interrupted in all States and UTs of India; and
- **By 2030**, malaria to be eliminated throughout the entire country, and re-establishment of transmission prevented.

**Programme phasing**

Malaria elimination in India will be carried out in a phased manner because the various States/UTs have different levels of malaria burden. While some low burden states are in a position to plan action for malaria elimination right now, the high burden states will need to reduce the malaria burden first before proceeding towards elimination. Therefore, States and UTs have been categorized into phases, based on their API as primary criterion with due consideration given to ABER and SPR as secondary criteria.

**Milestones and targets**

The milestones and targets set for malaria elimination in India are as follows:

**By the end of the year 2016**

- All States and UTs to have included malaria elimination in their broader health policies and planning framework.

**By the year 2020**

1. All 15 States/UTs that were under category 1 (elimination phase) in 2014 to completely interrupted malaria transmission and achieved zero indigenous cases and deaths due to malaria.
2. All 11 States/UTs under category 2 (pre-elimination phase) in 2014 to enter into category 1 (elimination phase);
3. 5 States/UTs under category 3 (intensified control phases) in 2014 to enter into category 2 (pre-elimination phase);
4. 5 States/UTs under category 3 (intensified control phase) in 2014 to reduce disease burden but continue to remain in category 3; and
5. Estimated malaria burden at national level to reduce by 15–20% as compared to 2014.

Additionally, states with stronger health systems such as Gujarat, Maharashtra and Karnataka may implement accelerated malaria elimination programmes to achieve interruption of transmission and demonstrate early elimination followed by sustenance of zero indigenous cases.

**By the year 2022**

1. All 26 States/UTs that were under categories 1 and 2 in 2014 to interrupt malaria transmission and achieved zero indigenous cases and deaths due to malaria:
2. 5 States/UTs which were under category 3 (intensified control phases) in 2014 to enter into category 1 (elimination phase);
3. 5 States/UTs which were under category 3 (intensified control phases) in 2014 to enter into category 2 (pre-elimination phase); and
4. Estimated malaria burden at national level reduced by 30–35% as compared to 2014.

**By the year 2024**

1. All States and UTs and their districts to reduce API to less than 1 case per 1000 population at risk, sustain zero
HEALTH PROGRAMMES IN INDIA

Deaths due to malaria and establish fully functional malaria surveillance to track, investigate and respond to each case;

1. States/UTs to interrupt transmission of malaria and zero indigenous cases and deaths attained; and
2. API > 0 to < 1
3. API 1 to < 2
4. API 2 to < 5
5. API ≥ 5

Strategies (4)

The overall objectives of the malaria elimination programme are rapid reduction of transmission in areas with high malaria incidence, interruption of malaria transmission in low transmission areas; and prevention of re-establishment of malaria in areas where transmission has been interrupted.

The broad strategies of the malaria elimination framework are:

- Early diagnosis and radical treatment
- Case-based surveillance and rapid response
- Integrated vector management (IVM)
  - Indoor residual spray (IRS)
  - Long-lasting insecticidal nets (LLINs) / Insecticide treated bed nets (ITNs)
  - Larval source management (LSM)
- Epidemic preparedness and early response
- Monitoring and evaluation
- Advocacy, coordination and partnerships
- Behaviour change communication and community mobilisation
- Programme planning and management

The key interventions recommended for each category of states/UTs are detailed below.

Category 3 (Intensified control phase. States/UTs with API ≥ 1)

1. Massive scaling up of existing disease management and preventive approaches and tools, aimed at a significant reduction in the prevalence and incidence of malaria as well as associated deaths.
2. Screening of all fever cases suspected for malaria
3. Classification of areas as per local malaria epidemiology and grading of areas as per risk of malaria transmission followed by implementation of tailored interventions.
4. Strengthening of intersectoral collaboration: Special interventions for high-risk groups such as tribal populations and populations residing in conflict affected or hard-to-reach areas.
5. One-stop centres or mobile clinics on fixed days in tribal or conflict affected areas to provide malaria diagnosis and treatment, and increasing community awareness with the involvement of other agencies and service providers as required.
6. Timely referral and treatment of severe malaria cases to reduce malaria-related mortality. Strengthening all district and sub-district hospitals in malaria endemic areas as per Indian Public Health Standards with facilities for management of severe malaria cases.
7. Establishment of a robust supply chain management system.
8. Maintenance of an optimum level of surveillance using appropriate diagnostic measures.
9. Equipping all health institutions (primary health care level and above), especially in high-risk areas, with microscopy facilities and RDTs for emergency use and injectable artemisinin derivatives for treatment of severe malaria.

Focus on High-Endemic Areas and Tribal Population:

Most of the malaria cases in India are reported from Andhra Pradesh, Chhattisgarh, Jharkhand, Madhya Pradesh, Maharashtra, Meghalaya, Mizoram, Odisha, Telangana and Tripura. The high incidence in these states is particularly noted in tribal populations living in foothills forested or conflict-affected areas. The malaria programme plans to scale up interventions in these areas along with innovative strategies.

Special strategy for P. vivax elimination (4)

India accounts for more than 50% of the estimated P. vivax cases in the world. Elimination of P. vivax from India is a serious challenge due to its magnitude as well as the need for a special strategy as P. vivax usually disappears from an area much after P. falciparum, because: (1) P. vivax hypnozoites prolong the parasite's lifespan and are difficult to detect; (2) RDTs currently available to detect P. vivax are less sensitive than RDTs for P. falciparum detection; (3) Radical treatment for P. vivax requires 14 days of primaquine therapy to kill the hypnozoites whereas treatment for P. falciparum can be completed in only 3 days; and (4) P. vivax strains have a longer incubation period.

The states and UTs with P. vivax preponderance will now initiate special measures for elimination of P. vivax by expanding bivalent RDTs and quality microscopy services to detect all P. vivax infections; ensuring compliance of the 14-day radical treatment by affected individuals; and tackling urban malaria by targeting An. stephensi by antilarval measures.

District as the unit of planning and implementation:

States and UTs should categorize their districts so that even if the given state/UT is not yet in the elimination phase, their districts with API < 1 could be considered eligible for initiating elimination phase activities. In addition, each district may sub-categorize its blocks into different phases based on their API; and further each block into its PHCs, PHC into SCs and SC to villages. This would facilitate some category 2 districts to start elimination activities in their blocks failing in category 1. Stratification may be done in this manner up to the subcentre level (4).

Each district should stratify its PHCs and sub-centres {with their population} into the following five strata, as those with:

1. Zero cases
2. API > 0 to < 1
3. API 1 to < 2
4. API 2 to < 5
5. API ≥ 5

By the year 2027

Indigenous transmission of malaria interrupted and the entire country to have no indigenous cases and no deaths due to malaria

By the year 2030

The entire country to sustain status of zero indigenous cases and deaths due to malaria for 3 consecutive years; and India to initiate the processes for certification of malaria elimination status.

2. API > 0 to < 1
3. API 1 to < 2
4. API 2 to < 5
5. API ≥ 5

Strategies (4)

The overall objectives of the malaria elimination programme are rapid reduction of transmission in areas with high malaria incidence, interruption of malaria transmission in low transmission areas; and prevention of re-establishment of malaria in areas where transmission has been interrupted.

The broad strategies of the malaria elimination framework are:

- Early diagnosis and radical treatment
- Case-based surveillance and rapid response
- Integrated vector management (IVM)
  - Indoor residual spray (IRS)
  - Long-lasting insecticidal nets (LLINs) / Insecticide treated bed nets (ITNs)
  - Larval source management (LSM)
- Epidemic preparedness and early response
- Monitoring and evaluation
- Advocacy, coordination and partnerships
- Behaviour change communication and community mobilisation
- Programme planning and management

The key interventions recommended for each category of states/UTs are detailed below.

Category 3 (Intensified control phase. States/UTs with API ≥ 1)

1. Massive scaling up of existing disease management and preventive approaches and tools, aimed at a significant reduction in the prevalence and incidence of malaria as well as associated deaths.
2. Screening of all fever cases suspected for malaria
3. Classification of areas as per local malaria epidemiology and grading of areas as per risk of malaria transmission followed by implementation of tailored interventions.
4. Strengthening of intersectoral collaboration: Special interventions for high-risk groups such as tribal populations and populations residing in conflict affected or hard-to-reach areas.
5. One-stop centres or mobile clinics on fixed days in tribal or conflict affected areas to provide malaria diagnosis and treatment, and increasing community awareness with the involvement of other agencies and service providers as required.
6. Timely referral and treatment of severe malaria cases to reduce malaria-related mortality. Strengthening all district and sub-district hospitals in malaria endemic areas as per Indian Public Health Standards with facilities for management of severe malaria cases.
7. Establishment of a robust supply chain management system.
8. Maintenance of an optimum level of surveillance using appropriate diagnostic measures.
9. Equipping all health institutions (primary health care level and above), especially in high-risk areas, with microscopy facilities and RDTs for emergency use and injectable artemisinin derivatives for treatment of severe malaria.
Category 2 (Pre-elimination phase: States UTs with API < 1, but some of their districts reporting API ≥ 1)

The states/UTs in pre-elimination phase are those close to entering the elimination phase. Therefore, malaria elimination interventions will be introduced with particular focus on setting up an elimination surveillance system and initiating elimination phase activities in those districts where the API has been reduced to less than 1 case per 1000 population at risk per year. The planning of elimination measures will be based on epidemiological investigation and classification of each malaria case and focus.

Category 1 (Elimination phase: States UTs with API < 1, and all their districts reporting API < 1)

1. All efforts will be directed at interrupting local transmission in all active foci of malaria.
2. Mandatory notification of each case of malaria from the private sector, other organized government sectors or any other health facility.
3. Adequate case-based surveillance and complete case management established and fully functional across the entire country to handle each case of malaria.
4. Investigation and classification of all foci of malaria.
5. A strict total coverage of all active foci by effective vector control measures.
6. Early detection and treatment of all cases of malaria by means of ACD and/or PCD to prevent onward transmission.
7. State and national-level malaria elimination database established and made operational.
8. Implementation of interventions for effective screening, management and prevention of malaria among mobile and migrant populations.
9. Establishment of an effective epidemic forecasting and response system.
10. Ensuring rigorous quality assurance of all medicines and diagnostics.
11. Setting up a national-level reference laboratory to serve following two functions:
   (a) All positive and a fixed percentage of negative slides will be referred to this laboratory for confirmation of diagnosis and cross-checking. After elimination has been achieved in each State/UT, 100% of cases will be notified to this laboratory for confirmation of diagnosis.
   (b) Training of master trainers and accreditation certification of microscopists as per Indian Public Health Standards shall also be undertaken at this laboratory.
12. During investigation of foci, all suspected cases of malaria are to be screened for malaria. These could include household members, neighbours, school children, workplace colleagues and relatives.
13. Surveillance of special groups, migrant populations or populations residing in the vicinity of industrial areas are also to be covered under surveillance operations.

Category 0 (prevention of re-establishment phase)

When any area, whether a state/UT or a district within a state/UT has, achieved malaria elimination, the specific objectives will be as follows:

1. Detect any re-introduced case of malaria.
2. Notify immediately all detected cases of malaria.
3. Determine the underlying causes of resumed local transmission.
4. Apply rapid curative and preventive measures.
5. Prevent re-introduction and possible re-establishment of malaria transmission; and
6. Maintain malaria-free status in these areas.

Surveillance (2, 4)

The malaria surveillance system in India was initially set up in the early 1960s. The system has since been adapted to the needs of control and now monitors malaria incidence trends and geographic distribution. The aim is to target control interventions in high transmission areas and assessing their impact. Surveillance also plays a key role in the early detection of outbreaks.

Active case detection (ACD) is carried out in rural areas with blood smears collected by MPWs/ANM during fortnightly house visits. Passive case detection (PCD) is done in fever cases reporting to peripheral health volunteers (ASHAs) and at sub-centres, malaria clinics, CHCs, and other secondary and tertiary level health institutions that patients visit for treatment. ACD and other volunteer workers provide diagnostic services by RDTs, and at PHCs by examination of blood smears. In villages where no ASHA or other volunteer has been trained and deployed for providing early diagnosis and effective treatment, ACD and case management is done by the MPWs.

The surveillance data of NVBDCP reflects malaria trends reasonably well because the ABER in the country as a whole has remained relatively constant at about 10%, and the surveillance system has not undergone any major changes. The ABER, however, low in a few states, while in most of the high endemic areas it is much above 10%. Microscopy remains the best method of diagnosis on account of its high sensitivity and specificity. It is also more economical in facilities where large number of slides are examined daily.

There are about 100 million blood slides collected from fever cases in India annually from which about 1.5 million malaria cases are detected. The new norms for case management emphasize quality care for patients. The implementation of use of Rapid Diagnostic Tests (RDTs) and Artemether-lumefantrine combination therapy (ACT) and the improvements in service delivery is expected to attract greater number of fever cases to the programme in the coming years. The programme also plans to supply RDT kits to private providers in return for data. The current level of screening of 100 million fever cases will not be reduced as it is aimed to screen 10% of the population, even though the disease transmission is expected to reduce.

During 2003, the NVBDCP introduced the use of RDT for early diagnosis of malaria. In the year 2012, bivalent RDT were introduced in the programme to detect P. vivax and P. falciparum. Since then, the programme has procured and distributed RDTs to community level workers/volunteers who have been trained to use them to enable timely diagnosis in these areas. In remote and inaccessible rural and tribal areas, RDTs are now the established method of choice for malaria diagnosis.

Parameters of malaria surveillance

By definition, surveillance also implies the continuing scrutiny of all aspects of occurrence and spread of a disease, that are pertinent to effective control. Included in these are...
the systematic collection and evaluation of field investigations, etc. The following parameters are widely used in the epidemiological surveillance of malaria: (a) Annual parasite incidence (API); (b) Annual blood examination rate (ABER); (c) Annual falciparum incidence (API); (d) Slide positivity rate (SPR); and (e) Slide falciparum rate (SFR).

Sentinel surveillance

One of the weaknesses of the existing malaria surveillance system is the lack of articulation with hospitals, which means that severe malaria cases are not reported separately and that only a small fraction of malaria deaths are recorded. Therefore, sentinel surveillance is being established in high endemic districts, by selecting in each district, depending on its size, 1-3 sentinel sites in large hospitals for recording of all out-patient and in-patient cases of malaria, and malaria related deaths.

Case management

According to the revised drug policy, there is no scope of presumptive treatment in malaria control. The new drug policy of 2013 is being followed in the country. For further details please refer to page 287, chapter 5.

Integrated vector management (IVM)

The NVBDCP aims to achieve effective vector control by the appropriate biological, chemical and environmental interventions of proven efficacy, separately or in combination as appropriate to the area through the optimal use of resources. Efforts are made for collaboration with various public and private agencies and community participation for vector control. Integration of IVM is done by using identical vector control methods to control malaria and leishmaniasis in rural areas, and malaria and dengue in urban areas, to achieve cost-effectiveness and synergy. The IVM includes safe use of insecticides and monitoring of insecticide resistance. The measures of vector control and protection include:

- Measures to control adult mosquitoes: Indoor Residual Spray (IRS).
- Anti-larval measures: chemical, biological and environmental.
- Personal protection: use of bed-nets, including insecticide treated nets.

The national malaria control program is currently using IRS as the primary method of vector control in rural settings and anti-larval measures in urban areas. Insecticide treated bed-nets have been introduced in the programme and the programme envisages a scale up in their use as vector control option for full population coverage, which will replace IRS in areas, where operational factors indicate that this method alone will give sufficient impact.

As much as possible, the village is to be the unit of intervention, but in some districts, data available with knowledge of ecological conditions may make it more rational to classify whole sub-centre areas as high-risk areas. High risk areas and populations will be defined at least annually. Such villages shall be protected by indoor residual spray and insecticide treated nets and the coverage will be more than 80 per cent, whatever may be the intervention.

The population living in areas with API ≥ 5 is planned to be covered by LLINs and population living in endemic areas, registering API ≤ 2 is covered with conventional nets treated with insecticides and IRS. Conventional nets treated with insecticides will continue to be used in areas registering API 2 to 5. IRS is still the preferred method of vector control in areas with very hot summers and where ITNs are not acceptable to population.

A population of about 80 million is at present being covered by IRS in the country. DDT is the insecticide of choice, in areas where the vector has shown resistance to DDT, the alternatives are malathion and synthetic pyrethroids. Two rounds of spraying are done for DDT and synthetic pyrethroids to provide protection during the entire transmission season, and in the case of malathion, three rounds of spraying are required. About 60 per cent of the high risk areas targeted under IRS are under coverage with DDT. The real coverage by IRS is, however, limited by the low community acceptance due to the white marks left on plastered surface, acrid smell associated with malathion, replastering of walls after completion of IRS etc.

Malaria paradigms/ecotypes (2)

The association between malaria and various ecological situations have been studied in India since the early part of the 20th century. There is considerable heterogeneity in malaria transmission characteristics between and within the states of the country, and many ecotypes/paradigms of malaria have been recognized. They are discussed in detail on page 281 chapter 5.

Presently, malaria burden in the country is highly concentrated in a few forest-tribal states and areas. In most of these states, vector control interventions are limited to villages with API ≥ 5 or other high risk criteria, due to resource constraints. The North-East has specific difficulties in implementation and monitoring due to various reasons. A transition of tribal population laws in inaccessible terrain, forest, hilly and riverbed conditions, and characterized by high degree of mobility, poverty, inadequate clothing, outdoor sleeping habits, forest based economy etc. Presence of efficient vectors, triple insecticide resistance and immunity as breeding sites add to the problem. Moreover, health infrastructure is generally found to be inadequate in these areas. All these factors maintain malaria as one of the most important cause of morbidity and mortality affecting tribal populations. The predominant parasite species in tribal areas is P. falciparum which is known to cause severity and lead to mortality if timely treatment is not provided.

A tribal-specific strategy is being envisaged to be implemented through a Tribal Malaria Action Plan (TMAP). Category 2 and 3 districts are planned to be covered initially. This will enable concentration of available resources to high endemic areas. The key interventions are as follows (4):

1. Strengthening surveillance: Introduction of mobile based surveillance, where routine health services/facilities are not available.
3. Wherever engagement of ASHAs is not possible, anganwadi workers of ICDS, faith healers, local medical, health care providers, village headmen, PIBs or school teachers may be trained and provided relevant logistics to diagnose and treat malaria cases. In forest areas, involvement of forest department in diagnosis and treatment may be done.
4. In areas with civic disturbance, provision of well-informed and pre-scheduled mobile health services.
5. Involvement of locally available, credible NGOs.
6. Strengthening of PHCs with quality microscopy facilities.
7. Provision of diagnosis and treatment facilities by
contractors/owners of development projects to the labours on site, should be made mandatory.

8. On the spot, species-specific radical treatment of all positive cases of malaria.

9. Identification of serious cases and early referral to specialized health facilities, ensuring free transport services.

10. Follow up and epidemiological tracking of all positive cases.

12. Integrated Vector Management (IVM) for appropriate vector control. Prioritization of villages according to degree of risk for taking appropriate vector control measures (IRS/LLINs or treatment of community-owned bed nets with insecticides).

13. Social marketing to increase usage of bed nets.

14. Minor environmental engineering like cleaning de-silting of drainage, filling pits and ditches, solid waste management through Village Health, Sanitation and Nutrition Committee (VHSN&C) as well as MNREGA.

15. Regular and efficient supply chain management.

16. Intensive training for all cadres of staff, ASHAs, community volunteers.

17. Community mobilization by utilizing traditional IEC-BCC tools and practices.

Table 2 summarizes the key indicators that will be used to measure the country's progress towards elimination at national and sub-national level.

**Behaviour change communication (BCC)**

BCC is a systematic process that motivates individuals, families and communities to change their inappropriate or unhealthy behaviour, or to continue a healthy behaviour. BCC is a key supportive strategy for malaria prevention and treatment under NVBDCP.

BCC is directed at: (a) early recognition of signs and symptoms of malaria; (b) early treatment seeking from appropriate provider; (c) adherence to treatment regimens; (d) ensuring protection of children and pregnant women; and (e) use of ITNs/LLINs; and (f) acceptance of IRS, etc.

**Anti-malaria month campaign**

Anti-malaria month is observed every year in the month of June throughout the country, prior to the onset of monsoon and transmission season, to enhance the level of awareness and encourage community participation through mass media campaign and inter-personal communication and consolidate inter-sectoral collaborative efforts with other government departments, corporate and voluntary agencies at national, state and district levels.

**Interaction of malaria control with other health programmes**

The other main public health programmes related to malaria control are:

1. Integrated Disease Surveillance Project (IDSP) - The project, with weekly fever alerts is increasingly providing the early warning signals on malaria outbreaks.

2. Other vector borne diseases: Dengue and malaria control activities overlap in many urban areas, malaria and kala-azar in a few districts of Jharkhand, and malaria and filariasis in some areas including a few districts of Odisha.

3. Reproductive and child health - Antenatal care services are utilized in distribution of LLINs to pregnant women in some areas of the country. Janani Suraksha Yojana also makes provision of bed-nets distribution to pregnant women. Changes in the malaria case management norms have been included in the Integrated Management of Neonatal and Childhood Illness.

**The major externally supported projects**

Additional support for combating malaria is provided through external assistance in high malaria risk areas. There were two such externally funded projects which were being implemented for malaria control:

1. Global Fund supported Intensified Malaria Control Project (IMCP II) - Global Fund Round 9 supported IMCP II was being implemented since October 2010 for a period of five years in 7 North East states. The project area covers a population of 46 million in 86 districts. The

Source: (5)
strategy of the project are early diagnosis and complete treatment, integrated vector control including promotion of ITN (LLINs).

Additional support provided in project area was as follows:

- **Human resource** such as consultants and support staff for project monitoring units at state and district level and medical technical supervisor and laboratory technicians at sub-district level;

- **Capacity building** of Medical Officers Lab Technicians Fever Treatment Depots volunteers etc.

- **Commodities** such as long-lasting insecticidal nets (LLINs), rapid diagnostic tests for quick diagnosis of malaria, alternative drugs (Artesunate Combination Therapy, inj. Arteether) for treating severe malaria cases; and

- Planning and administration including mobility support, monitoring, evaluation and operational research (studies on drug resistance and entomological aspects).

(iii) World Bank supported project on Malaria Control & Kala-azar Elimination. The programme was in operation for five years since 2009 to 31.12.2013.

(B) ELIMINATION OF LYMPHATIC FILARIASIS

The disease is endemic in 256 districts in 16 states and 5 UTs. According to recent estimates about 630 million people are exposed to the risk of infection (7).

The National Filaria Control Programme has been in operation since 1955. In June 1978, the operational component of the NFCP was merged with the urban malaria scheme for maximum utilisation of available resources. The training and research components, however, continue to be with the Director, National Institute of Communicable Diseases, Delhi.

Training in filariology is being given at three Regional Filaria Training and Research Centres situated at Calicut (Kerala), Rajahmundry (A.P) and Varanasi (U.P) under the National Institute of Communicable Diseases, Delhi. Besides, 12 headquarters bureaux are functioning at the state level.

Filaria control strategy includes vector control through anti larval operations, source reduction, detection and treatment of *Wuchereria bancrofti* carriers, morbidity management and IEC. National Filaria Control Programme is being implemented through 205 filaria control units, 199 filaria clinics and 27 survey units, primarily in endemic urban towns in rural areas anti filaria medicines and morbidity management services are provided through primary health care system.

In India, the National Health Policy (2002) envisages elimination of lymphatic filariasis (ELF) by 2015. The elimination is defined as "lymphatic filariasis ceases to be a public health problem, when the number of microfilaria carriers is less than 1 per cent and the children born after initiation of ELF are free from circulating anti LF antibodies (presence of adult filaria worm in human body)

The strategy of lymphatic filariasis elimination is through:

(a) Annual Mass Drug Administration (MDA): of single dose of antifilarial drug for 5 years or more to the eligible population (except pregnant women, children below 2 years of age and seriously ill persons) to interrupt transmission of the disease.

(b) Home based management of lymphoedema cases and up scaling of hydrocele operations in identified CHCs/ district hospitals/medical colleges.

To achieve elimination of lymphatic filariasis, during 2004 the Govt. of India launched annual MDA with single dose of DEC tablets in addition to scaling-up home based foot care and hydrocele operation. The co-administration of DEC + Albendazole has been upscaled since 2007. The programme covered 202 districts in 2004 whereas by the year 2007 all the 230 LF endemic districts were covered. The mass drug administration starts in the month of November and the coverage has improved from 72.4 per cent in the year 2004 to 86.8 per cent in 2014.

The achievement is significant as till August 2017, 94 districts with 152 evaluation units (approximately 221 million population) have successfully completed 1st Transmission Assessment Survey (TAS) and stopped MDA. 20 more districts were to observe 1st TAS during 2017 (7).

The line listing of lymphoedema and hydrocele cases were initiated since 2004 by door-to-door survey in filaria endemic districts. The updated figure till December 2014 reveals about 12.5 lakh cases with clinical manifestation of filariasis were line listed which includes 8.7 lakh cases of lymphoedema and 3.8 lakh cases of hydrocele. Initiation has also been taken to demonstrate the simple washing of foot to maintain hygiene for prevention of secondary bacterial and fungal infection in chronic lymphoedema cases, so that the patients get relief from frequent acute attacks.

The microfilaria survey in all the implementation units is being done through night blood survey before MDA. The survey is done in 4 sentinel and 4 random sites collecting total 4000 slides (500 from each site). There is definite evidence of microfilaria reduction in the MDA districts. However, the coverage of population with MDA should be above 80 per cent primarily for 5-6 years, which would reduce microfilaria load in the community and thereby, interrupt the transmission (3).

(C) KALA-AZAR

Kala-azar is now endemic in 33 districts of Bihar, 4 districts of Jharkhand, 11 districts of West Bengal and 6 districts of Uttar Pradesh, besides sporadic cases in few other districts of Uttar Pradesh. A centrally sponsored programme was launched in 1990-91. This has brought down the incidence of the disease from 77,102 cases in 1992 to 5,758 cases in 2017 (7).

The strategies for Kala-azar elimination are: (a) Enhanced case detection and complete treatment including introduction of rK39 rapid diagnostic kits and oral drug Miltefosine for treatment of Kala-azar cases; (b) Interruption of transmission through vector control. It has been decided to replace DDT with alternate pyrethroid for the purpose of fogging to eliminate sandfly, as the insect is becoming resistant to DDT; (c) Communication for behavioural impact and intersectoral convergence; (d) Capacity building; (e) Monitoring, supervision and evaluation; and (f) Research guidelines on prevention and control of Kala-azar have been developed and circulated to the states.

ACTIVE CASE SEARCH The frequency of case searches has been increased from a single annual case search to quarterly case searches. The active case searches are carried out during a fortnight designated as the "Kala-azar Fortnight", during which the peripheral health workers and volunteers are engaged to make door-to-door search and refer the cases conforming to the case definition of kala-azar and PKDL to the treatment centres for definitive diagnosis and treatment (3).
An incentive amount of Rs. 300 is provided to ASHA for identifying each case of kala-azar and Rs. 100 for ensuring one round and Rs. 200 for two rounds of insecticide spraying. Even the patient being treated in the hospital will be given Rs. 300 as compensation of daily wage for the time he spends in the hospital during the treatment for kala-azar and Rs. 2000 for PKDL. This revised strategy of total eradication of kala-azar was launched on 2nd September 2014.

The new strategy also includes introduction of Rapid Diagnostic Kit developed by ICMR into the programme and single dose treatment with Liposomal Amphotericin B, which is given intravenously in 10 mg/kg dose. It is to reduce the human reservoir of infection. WHO will supply the drug free of cost (8).

(D) JAPANESE ENCEPHALITIS

Japanese encephalitis is a disease with high mortality rate and those who survive do so with various degrees of neurological complications. During the last few years, Japan has become a major health problem. States of Uttar Pradesh, West Bengal, Assam, Tamil Nadu, Karnataka, Bihar, Maharashtra, Manipur, Harvana, Kerala and Uttar Pradesh are reporting maximum number of cases.

The strategies for prevention and control of Japanese encephalitis include strengthening of the surveillance activities through sentinel sites in tertiary health care institutions, early diagnosis and proper case management. Integrated vector control, particularly personal protection and use of larvivorous fishes, capacity building and behaviour change communication. As the JE vectors are outdoor vectors, indoor residual spray is not effective. The government of India provides need-based assistance to the states, including support for training programmes and social mobilization.

As there is no specific cure for the disease, early case management is very important to minimize the risk of complications and death. JE vaccination is recommended for children between 1 to 15 years of age. In addition, health education through different media and interpersonal communication for the community is crucial. Emphasis should be given on keeping pigs away from human dwellings or in pigsties, particularly during dusk to dawn, which is the biting time of vector mosquitoes. Use of clothes which cover the body fully to avoid mosquito bites are advocated. Use of bed-nets is also very important precaution. Since early reporting of cases is important to avoid complications, the community should be given full information about the signs and symptoms of the disease, and the health facilities available at health centres/hospitals. The states are advised to use malathion for outdoor fogging as the outbreak control measure in the affected areas (9). Epidemiological monitoring of the disease for effective implementation of preventive and control measure and technical support is provided on request by the state health authorities.

(E) DENGUE FEVER/ DENGUE HAEMORRHAGIC FEVER

During 1996, an outbreak of dengue was reported in Delhi. Since then dengue has been reported from other states also. In view of this major outbreak of the disease a "Guideline of Preparation of Contingency Plan in case of outbreak/epidemic of Dengue/Dengue haemorrhagic fever" was prepared and sent to all the states. It includes all the important aspects of control measures like identification of outbreak, demarcation of affected area, containment of outbreak, case management, vector control, IEC activities about Do's and Don'ts for prevention of dengue, monitoring and reporting etc.

Since early reporting of cases is crucial to avoid any complication and mortality, the community is given full information about the signs and symptoms as well as availability of health services at health centres/hospitals. Assistance is given to hospitals for making up arrangements for management of dengue/dengue haemorrhagic fever cases. This strategy of total eradication has been advised.

Government of India in consultation with states has identified 521 sentinel surveillance hospitals with laboratory support for augmentation of diagnostic facilities in the endemic states. Further, for advanced diagnosis and backed-up support 14 Apex Referral Laboratories have been identified and linked with sentinel surveillance hospitals. To make these functional, 20 rapid capture ELISA test kits have been provided through National Institute of Virology, Pune free of cost. Contingency grants are also provided to meet the operational costs.

For early diagnosis ELISA based NS1 kits have been introduced under the programme which can detect the cases from 1st day of infection. IgM capture ELISA tests can detect the cases after 5th day of infection.

The GOI has taken the following steps for prevention and control of dengue (6):

- **Monitoring** the situation through reports received from state health authorities.
- A mid-term plan for prevention and control of dengue has been developed in 2011 and circulated to the states for implementation. The main components of mid-term plan for prevention and control of dengue are as follows:
  - (a) **Surveillance**: Disease and entomological surveillance.
  - (b) **Case management**: Laboratory diagnosis and clinical management.
  - (c) **Vector management**: Environmental management for source reduction, chemical control, personal protection and legislation.
  - (d) **Outbreak response**: Epidemic preparedness and media management.
  - (e) **Capacity building**: Training, strengthening human resource and operational research.
  - (f) **Behavioural change communication**: Social mobilization, information, education and communication (IEC).
  - (g) **Inter-sectoral coordination**: with ministry of urban development, rural development, panchayati raj, surface transport and education sector.
  - (h) **Monitoring and supervision**: Analysis of reports, review, field visit and feedback.

(F) CHIKUNGUNYA FEVER

Chikungunya fever is a debilitating non-fatal viral illness that re-emerging in the country after a gap of three decades. Govt. of India is continuously monitoring the situation. Guidelines for prevention and control of the disease have been prepared. Since same vector is involved in the transmission of dengue and chikungunya, strategies for transmission risk reduction by vector control are also the same. Support in the form of logistics and funds are provided to the states.

For carrying out proactive surveillance and enhancing diagnostic facilities for chikungunya, the 521 sentinel
The National Leprosy Control Programme (NLCP), has been in operation since 1955, as a centrally aided programme to achieve control of leprosy through early detection of cases and DDS (dapsone) monotherapy on an ambulatory basis. The NLCP moved ahead initially at a slow pace, presumably for want of clear-cut policies or operational objectives for nearly two decades (10). The programme gained momentum during the Fourth Five Year Plan after it was made a centrally-sponsored programme. In 1980 the Government of India declared its resolve to eradicate leprosy by the year 2000 and constituted a Working Group to advise accordingly. The Working Group submitted its report in 1982 and recommended a revised strategy based on multi-drug chemotherapy aimed at leprosy eradication through reduction in the quantum of infection in the population, reduction in the sources of infection, and breaking the chain of transmission of disease. In 1983 the control programme was redesignated National Leprosy “Eradication” Programme with the goal of eradicating the disease by the turn of the century. The aim was to reduce case load to 1 or less than 1 per 10,000 population.

To strengthen the process of elimination of leprosy in the country, the first World Bank supported project was introduced in 1993. On completion of this project, the 2nd phase of project with World Bank support was started in 2001–02 which ended in December 2004. Since then, the programme is being continued with Government of India funds with technical support from WHO and International Federation of Anti-Leprosy Association (ILEP) organizations. The programme has been integrated with general health care system in 2002–03, since then leprosy diagnosis and treatment services are available at all PHCs and government hospitals.

The components of the programme are as follows:

1. Decentralized integrated leprosy services through general health care system;
2. Capacity building of all general health services functionaries;
3. Intensified information, education and communication;
4. Prevention of disability and medical rehabilitation; and
5. Intensified monitoring and supervision.

After introduction of MDT, the recorded case load of leprosy came down from 57.6 cases per 10,000 population in 1981 to less than one at the national level in December 2005. and the country could achieve the goal of leprosy elimination at national level as set by the National Health Policy (2002). 34 states UTs achieved the status of leprosy elimination. Only 2 states UTs viz. Chattisgarh and Madia & Nagri Haveli are yet to achieve elimination Bihar, Goa, Chandigarh and Odisha, who have achieved elimination status earlier, show PR > 1 per 1000 population (11).

A total of 209 high endemic districts were identified for special action during 2012–13. 1792 blocks and 150 urban areas were identified for special activities, i.e., house to house survey along with IEC and capacity building of the workers and volunteers (11).

Major initiatives taken are as follows:

1. More focus has now been given to new case detection than prevalence which only gives the number of cases on record at a point in time. The new case detection rate is the main indicator for programme monitoring.
2. Treatment completion rate has been taken as an important indicator, to be calculated by states at yearly basis.
3. More emphasis is being given on providing disability prevention and medical rehabilitation (DPMR) services to leprosy affected persons. The aid provided is as follows:
   a. Dressing materials for visible manipulative deformities of hands, feet or eye — Rs. 250/-.
   b. Non-surgical prosthesis — Rs. 500/-.
   c. Surgery (excluding hospitalization) for visible deformities — Rs. 2500/-.
   d. Support is also provided to government institutions/PMR centres in the form of Rs. 5000/- per reconstructive surgery conducted.

(4) ASHAs have been involved in bringing out suspected leprosy cases from their villages for diagnosis and treatment at PHC and follow-up of confirmed cases for their treatment completion. To facilitate the involvement of ASHA in the programme, they are being paid incentive money as below:

a. On confirmed diagnosis of case brought by them — Rs. 250/-.
b. On completion of cure course of treatment of the case within specified time — PB leprosy case Rs. 400/-; and MB leprosy case Rs. 600/-
   c. An early case before onset of any visible deformity — Rs. 250/-
   d. A new case with visible deformity in hands, feet or eye — Rs. 200/-

Activities to be performed by ASHA are as follows:

a. Search for suspected cases of leprosy i.e. before any sign of disability appears. Such early detection will help in prevention of disability and also cut down transmission potential.
   b. Follow up all cases for completion of treatment in scheduled time. During follow up visit, also look for symptoms of any reaction due to leprosy and refer them to the Health Workers PHC for treatment. This will again reduce chances of disability occurring in cases under treatment.
   c. Advise and motivate self-care practices by disabled cases for proper care of their hands, feet during the follow-up period. This will improve quality of life of the affected persons and prevent deterioration of disabilities.
   d. Spreading awareness.
   e. There are 612 self settled colonies in the country where more than 50,000 leprosy affected persons reside. Free medical facilities like care of ulcers, self...
care training, counselling and MCR footwear are provided to leprosy affected persons residing in these colonies through para-medical workers/NGOs on weekly/fortnightly basis.

6. Intensive IEC campaign with a theme "Towards Leprosy Free India" has been carried out towards further reduction of leprosy burden in the community, early reporting of cases and their treatment completion, provision of quality leprosy services and reduction of stigma and discrimination against leprosy affected persons. Awareness generation activities are carried out through mass media and local media.

Disability prevention and medical rehabilitation (DPMR)

The main activities carried out under DPMR are as follows (12):

1. Implementation of DPMR activities as per guidelines and reporting its outcome e.g. treatment of leprosy reaction, ulcers, physiotherapy, reconstructive surgery and providing MCR footwear.
2. Integrating DPMR services - There are provision of services to persons with disability by various departments under different ministries. Convergence of NLEP services into NRHM facilitates this integration.
3. To develop a referral system to provide prevention of disability services to all leprosy disabled persons in an integrated set-up.

The DPMR activities are planned to be carried out in a three tier system i.e. the primary level care (First level), secondary level care (Second level) and the tertiary level care (Third level). The primary level care institutions are all PHCs, CHCs. Sub-divisional hospitals and urban leprosy centres dispensary. The secondary level care institutions are all District Head Quarter Hospitals and District Nucleus Units. The tertiary level care institutions are:

2. ICMR Institute JALMA, Agra.
3. ILEP supported Leprosy Hospitals.
4. All PMR Institutes and departments of medical colleges.

The other support units are:

1. Orthopaedics and plastic surgery departments of medical colleges.
2. Identified NGO institutions.
3. All National Institutes under Ministry of Social Justice and Empowerment.
4. Contractual surgeons skilled in RCS and Rehabilitation Programmes.

The referral system in NLEP is as shown in Fig. 1.

Decentralization and Institutional development: Integration of leprosy services into the general health care system has been completed. Services are available from all PHCs, and other health centres where a medical officer is available. District nucleus has been formed to supervise and

![Referral System in NLEP](source:12)
monitor the programme. State leprosy societies formed will merge with the state health society under the National Rural Health Mission.

**Services in the urban areas (13)**

The health services in the urban areas differ from the rural areas because of non-availability of infrastructure like PHC and manpower for providing services up to domiciliary level. The services in urban areas are provided mainly through institutional level. Multiple organizations provide health services in urban localities without much of coordination amongst them.

More number of cases are detected in urban localities due to migration of people, availability of good quality institutions with easy accessibility, but treatment completion rate is less as compared to rural areas.

For the implementation of special action under the plan, about 524 urban localities have been identified out of 4,388 urban areas (census 2011). These localities are having population more than 100,000. Remaining areas will be covered by PHC services as in rural areas (13). These urban areas are divided into 4 categories: (a) Town and city (population 1 lac to 5 lacs) – 432 areas; (b) Medium city (population >5 lac to 1 million) – 53 areas; (c) Mega city (population >1 million to 4.5 million) – 34 areas; and (d) Areas with >4.5 million population – 5 areas.

**Programme Implementation Plan for 12th Plan Period (2012-13 to 2016-17)**

As the disease is still prevalent with moderate endemicity in about 15 percent of the country, the plan objectives are set as follows (13).

- **Elimination of leprosy** i.e. prevalence of less than 1 case per 10,000 population in all districts of the country.
- **Strengthen disability prevention and medical rehabilitation of persons affected by leprosy.**
- **Reduction in the level of stigma associated with leprosy.**

**Targets (13)**

The plan targets are as shown in Table 3.

<table>
<thead>

</tbody>
</table>
| Gr II disability rate in percentage of new cases | 3.04% | 35% reduction over the baseline (NSS 2010-11)**
| Stigma reduction | Percentage reported by NSS | 50% reduction reported by NSS |

* Gr-II disability rate among new cases per million population to be reduced by 35% i.e. from 3 (2011-12) to 2 per million population by end of the 12th Plan.

** Based on the National Sample Survey (NSS) report, 2010-11.

**Programme strategy (13)**

To achieve the objectives of the plan, the main strategies to be followed are:

- Integrated leprosy services through general health care system.
- Early detection and complete treatment of new leprosy cases.
- Carrying out house-hold contact survey for early detection of cases.
- Involvement of Accredited Social Health Activist (ASHA) in the detection and completion of treatment of leprosy cases on time.
- Strengthening of disability prevention and medical rehabilitation (DPMR) services.

**Case detection and management (13)**

It is expected that the new cases will continue to occur regularly but the people are still hesitant to come forward to get themselves diagnosed and treated due to the stigma associated with the disease. Detection of the new cases at the early stage is the only solution to cut down the transmission potential in the community, and also to provide relief to the leprosy affected persons by preventing disabilities. It is therefore suggested that the states will draw up innovative plans:

(i) To improve access to services.
(ii) To involve women, including leprosy affected persons in case detection.
(iii) To organize skin camps for detecting leprosy patients while providing services for other skin conditions.
(iv) To undertake contact survey to identify the source in the neighbourhood of each child or multibacillary case.
(v) To increase awareness through the ANM, AWW, ASHA and other health workers visiting the villages and people affected by leprosy, to motivate leprosy affected persons for early reporting to the medical officer.

Integrated leprosy services through all the primary health care facilities will continue to be provided in the rural areas. However, for providing technical support to the primary health care system, to strengthen the quality of services being provided, a team of dedicated workers including medical officer and para-medical workers are placed at district level. This will be known as “District Leprosy Cell”.

Three pronged strategy was introduced in the National Leprosy Eradication Programme from 2016-2017. The components of the strategy are:

1. Leprosy Case Detection Campaign (LCDC);
2. Focused Leprosy Campaign; and
3. Special plan for hard to reach areas.

During 2016-17, LCDC was carried out in 163 districts of 20 states, wherein 34,672 cases were detected and were put on treatment. The activity was aimed at early case detection and timely treatment. The success of the campaign, as shown by the drastic decline of grade 2 disability, led to continuation of LCDC and during 2017-18 about 305 districts in 23 states were identified for LCDC phase I (14).

In the year 2016-17, Focused Leprosy Campaign was carried out by house to house survey in the village/ urban areas (covering 300 households) wherein one case of grade 2 disability due to leprosy was detected.

The purpose of the special plan for hard to reach areas is to find the cases in population in areas of difficult terrains, navalite affected areas and other geographically difficult locations (14).
Sparsh leprosy awareness campaign

Sparsh leprosy awareness campaign was launched in the year 2017 through Gram Sabhas and carried out with the help of Panchayat and Village Health and Sanitation Community. The aim was to generate awareness, reduce stigma and improve self-reporting of the cases. The campaign activity was carried out in 60 per cent of the total village across India (7). The campaign was to continue during the year 2018.

Survey education and treatment (SET) scheme

Under the SET scheme, the NGOs are presently involved in disability prevention and ulcer care, IEC, referral of suspected cases, referral for reconstruction surgery (RCS), research and rehabilitation. NGO support is mainly required for follow-up of under treatment cases in urban locations and difficult to reach areas.

Incentive to patient (7)

An incentive of Rs. 8000 will be paid to all patients affected by leprosy undergoing major reconstructive surgery irrespective of their financial status. The payment will be made by the district leprosy officer. As on January 2017, there were 115 recognized RCS centres (61 Government and 54 NGO) in the country.

Information, education and communication (IEC/BCC)

The IEC strategy during the 12th plan period was focus on communication for behavioural changes in general public against the stigma and discrimination against the leprosy affected persons. Making the public aware about the availability of MDT, correction of deformity through surgery and that the leprosy affected person can live a normal life with the family.

Research into the basic problems of leprosy is also part of the activities of the NLEP. This is mainly carried out in the Government sector, viz, the Central JALMA Institute of Leprosy, at Agartala and the Central Leprosy Teaching and Training Institute at Chinpattu, Chennai supported by Regional Training and Referral Institutes at Aska (Orissa), Raipur (Chhattisgarh) and Goupur (West Bengal).

ILEP Agencies

The International Federation of Anti-Leprosy Associations is actively involved as partner in NLEP in India. ILEP is constituted by 10 agencies viz. The Leprosy Mission, Damien Foundation of India Trust, Netherland Leprosy Relief, German Leprosy Relief Association, Lepra India, ALES, AIFO, Fontilles-India, AERF-India and American Leprosy Mission. ILEP is providing support in the form of planning, monitoring and supervision of the programme, capacity building of general health care staff, IEC, providing reconstructive surgery services and socio-economic rehabilitation of persons affected with leprosy. 36 NGOs conducting reconstructive surgeries for disability correction in leprosy affected persons are also supported by ILEP (12).

Non Government Organizations have been involved in the programme for many decades and have provided valuable contribution in reducing the burden of leprosy. Presently, 54 NGOs are getting grant-in-aid from Government of India under SET scheme. NGOs serve in remote, inaccessible areas, urban slums, industrial labour population and other marginalized population groups. IEC, prevention of disability, case detection and referral, and follow-up for treatment completion are some important activities taken up by NGOs (1).

The leprosy scene in India is passing through an important phase of transition - from a high burden country of leprosy to a relatively low burden country, from a partially vertical programme to a more integrated one, from a programme aimed at increase in coverage for leprosy services to one of sustaining quality services, and from centralization to decentralization (15).

Recently WHO has announced Global Leprosy Strategy 2016-2020 “Accelerating towards a leprosy free world” for further reducing the disease burden due to leprosy. Please refer to page 343 for details.

REVIEW NATIONAL TUBERCULOSIS CONTROL PROGRAMME

National Tuberculosis Programme (NTP) has been in operation since 1962. However, the treatment success rates were unacceptably low and the death and default rates remained high. Spread of multidrug resistant TB was threatening to further worsen the situation. In view of this, in 1992 Government of India along with WHO and SIDA reviewed the TB situation in the country and came up with following conclusions:

- NTP, though technically sound, suffered from managerial weaknesses
- Inadequate funding
- Over-reliance on X-ray for diagnosis
- Frequent interrupted supplies of drugs
- Low rates of treatment completion

In 1993, in order to overcome these lacunae, the Government of India decided to give a new thrust to TB control activities by revitalizing the NTP, with the assistance from international agencies. The Revised National TB Control Programme (RNTCP) thus formulated, adopted the internationally recommended Directly Observed Treatment Short-course (DOTS) strategy, as the most systematic and cost-effective approach to revitalize the TB control programme in India. Political and administrative commitment, to ensure the provision of organized and comprehensive TB control services was obtained. Adoption of smear microscopy for reliable and early diagnosis was introduced in a decentralized manner in the general health services. DOTS was adopted as a strategy for provision of treatment to increase the treatment completion rates. Supply of drugs was also strengthened to provide assured supply of drugs to meet the requirements of the system (16).

The objectives of the RNTCP are:

1. Achievement of at least 85 per cent cure rate of infectious cases of tuberculosis, through DOTS involving peripheral health functionaries; and
2. Augmentation of case finding activities through quality sputum microscopy to detect at least 70 per cent of estimated cases.

The revised strategy was introduced in the country in a phased manner as Pilot Phase I, Pilot Phase II and Pilot Phase III. By the end of 1998, only 2 per cent of the total population of India was covered by RNTCP. Large-scale implementation began in late 1998. The RNTCP has expanded rapidly over the years and since March 2006, it covers the whole country. The RNTCP has now entered into its second phase in which the programme aims to consolidate the gains made to date, to
Many of the initiatives like developing and piloting the feasibility of National Airborne Infection Control Guidelines, developing and piloting strategy for 'Practical Approach to Lung Health' are the examples of initiatives taken by RNTCP under the comprehensive strategy of STOP TB (16).

In 2014, the World Health Assembly unanimously approved to end global TB epidemic by "End TB Strategy", a 20 year programme with vision of a world with zero death, disease and suffering due to TB. For details please refer to page 219.

**ORGANIZATION**

The profile of RNTCP in a state is as follows:

- **State Tuberculosis Office**
  - State Tuberculosis Officer
- **State Tuberculosis Training and Demonstration Centre**
  - Director
- **District Tuberculosis Centre**
  - Medical Officer – TB Control
  - Senior Treatment Supervisor
  - Senior TB Laboratory Supervisor
- **Microscopy Centres, Treatment Centres**
- **DOTS Providers**

**RNTCP Organogram**

RNTCP structure comprises of five levels: National, state, district, sub-district and peripheral health institute levels as shown in Fig. 2 (17).

![Organogram](image_url)
LABORATORY NETWORK

Quality Assured Laboratory services: RNTCP has established a nationwide laboratory network, encompassing over 14,000 designated sputum microscopy centres (DMCs), which are being supervised by intermediate reference laboratories (IRL) at state level, and national reference laboratories (NRL) and central TB division at the National level. RNTCP aims to consolidate the laboratory network into a well-organized one, with a defined hierarchy for carrying out sputum microscopy with external quality assessment (EQA). The structure of laboratory network at different levels is as shown in Fig. 3.

National Reference Laboratories (NRL): The six NRLs under the programme are National Institute for Research in Tuberculosis (NIRT) Chennai; National Tuberculosis Institute (NTI), Bangalore; Lala Ram Swarup Institute of Tuberculosis and Respiratory diseases (LRS), Delhi; JALMA Institute, Agra; Regional Medical Research Centre, Bhubaneswar; and Bhopal Memorial Hospital and Research Centre, Bhopal (19). The NRLs work closely with the IRLs, monitor and supervise the IRL’s activities and also undertake periodic training for the IRL staff in EQA, Culture & DST, LPA and CBNAAT activities.

Three microbiologists and four laboratory technicians have been provided by the RNTCP on contractual basis to each NRL for supervision and monitoring of laboratory activities. The NRL microbiologist and laboratory supervisor/technician visits each assigned state at least once a year for 2 to 3 days as a part of on-site evaluation under the RNTCP EQA protocol.

Intermediate reference laboratory (IRL): One IRL has been designated in the state tuberculosis training and demonstration centres (STDC)/public health laboratory/medical college of the respective state. The functions of IRL are supervision and monitoring of EQA activities, mycobacterial culture and DST, and also drug resistance surveillance (DRS) in selected states. The IRL ensures the proficiency of staff in performing smear microscopy activities by providing technical training to district and sub-district laboratory technicians and senior TB laboratory supervisors (STLSs). The IRLs undertake on-site evaluation and panel testing to each district in the state, at least once a year.

Designated microscopy centre (DMC): The most peripheral laboratory under the RNTCP network is the DMC which serves a population of around 100,000 (50,000 in tribal and hilly areas). Currently all the districts in the country are implementing EQA. For quality improvement purposes, the NRL on-site evaluation (OSE) recommendations to IRLs and districts are discussed in the RNTCP laboratory committee meetings, quarterly at CTD. Quality improvement workshops for the state level TB officers and laboratory managers are conducted at NRLs based on the observations.
of the NRL-OSEs. These workshops focus on issues such as human resources, trainings, AMC for binocular microscopes, quality specifications for ZN stains, RBRC binding and coding issues, bio-medical waste disposal, infection control measures etc.

The Quality Assurance activities include:
- On-site evaluation.
- Panel testing and
- Random blinded rechecking.

Culture and DST laboratories (C & DST) (7, 18)

In addition to IRLs, the RNTCP also involves the microbiology department of medical colleges for providing diagnostic services for the drug resistant TB, extra-pulmonary TB and research. There are 69 RNTCP certified C & DST laboratories in the country which includes laboratories from public sector (IRLs and medical colleges, private sector and operated by NGOs).

Solid culture certification : The RNTCP has certified 46 laboratories for solid C & DST. These include 6 NRLs, 22 IRLs, 7 medical colleges, 5 NGOs, 4 ICMM institutes and 3 private laboratories.

Liquid culture certification : The RNTCP has certified 34 laboratories for liquid culture, which include 4 NRLs, 17 IRLs, 6 medical colleges, one NGO laboratory and 5 private laboratories.

Line Probe Assay (LPA) : The LPA is a molecular diagnostic test, which can provide the DST results within one day. The RNTCP has adopted the policy for rapid diagnosis of MDR-TB by LPA. As on December 2015, about 54 laboratories have been certified by RNTCP, these include 6 NRLs, 24 IRLs, 17 medical colleges, 5 NGO laboratories and 6 private medical college.

Second line DST (SLD) : As on December 2017, 27 laboratories which includes 5 NRLs, 14 IRL, one NGO laboratory and one private laboratory are performing second line DST in solid and liquid culture.

Expanding CBNAAT services: The time to diagnosis of TB and drug resistant TB has been significantly reduced with the availability of CBNAAT, which is a rapid molecular assay that detects M. tuberculosis and Rifampicin resistance. The test is fully automated and provides results in two hours. Currently, there are 671 machines providing services to the programme. To enhance laboratory capacity for the diagnosis of MDR- TB and TB in special population groups such as children and HIV/AIDS cases, additional CBNAAT machines have been provided by the Govt. of India to cover all states (20).

RNTCP endorsed TB diagnostics (1)

1. Smear microscopy for acid fast bacilli.
   a. Sputum smear stained with Ziehl-Neelsen staining; or
   b. Fluorescence stains and examined under direct or indirect microscopy with or without LED.
2. Culture
   a. Solid (Lowenstein Jansen) media; or
   b. Liquid media (Middle Brook) using manual semi-automatic or automatic machines, e.g., Bactec, MGIT etc.
3. Rapid diagnostic molecular test
   a. Conventional PCR based Line Probe Assay for MTB complex; or
   b. Real-time PCR based Nucleic Acid Amplification Test NAAT for MTB complex, e.g. GeneXpert.
4. Radiography where available.
5. Tuberculin skin test

New Initiatives

1. NIKSHAY: TB surveillance using case based web based IT system (19)

   Central TB Division in collaboration with National Informatics Centre has undertaken the initiative to develop a case based web based application named Nikshay. The word is combination of two Hindi words NI and KSHAY, meaning eradication of TB.

   This software was launched in May 2012 and has following functional components.

   - Master management
   - User details
   - TB Patient registration and details of diagnosis, DOT provider, HIV status, follow-up, contact tracing, outcomes.
   - Details of solid and liquid culture and DST, LPA, CBNAAT details.
   - DR-TB patient registration with details.
   - Referral and transfer of patients.
   - Private health facility registration and TB notification.
   - Mobile application for TB notification.
   - SMS alerts to patients on registration.
   - SMS alerts to programme officers.
   - Automated periodic reports
     a. Case finding
     b. Sputum conversion
     c. Treatment outcome.

   The programme has started using IT enabled adherence tools like 99 DOTS for HIV-TB patients. This will be expanded to all TB patients with implementation of daily regimen (7).

2. TB Notification

   In order to ensure proper diagnosis and management of TB cases, and to reduce TB transmission and the emergence and spread of MDR-TB, it is essential to have complete information of all TB cases. According to the Government of India notification dated 7th May 2012, it is now mandatory for all healthcare providers to notify every TB case to local authorities i.e., District Health Officer, Chief Medical Officer of a district and Municipal health officer, every month in a given format (21).

3. Ban on TB Serology

   The serological tests are based on antibody response, which is highly variable in TB and may reflect remote infection rather than active disease. Currently available serological tests are having poor specificity and should not be used for the diagnosis of pulmonary or extra-pulmonary TB. Their import, manufacturing, sale, distribution and use is banned by the Government of India (19).

4. Direct benefit transfer schemes

   Direct beneficiary transfer systems are being established by linking TB patients reported in NIKSHAY with AADHAR and PEMS to effectively deliver benefits to TB patients and their providers (7).
Initiation of treatment

Early identification of people with high probability of having active TB (presumptive TB) is the most important activity of the case finding strategy. Patients presenting themselves with symptoms suspicious of tuberculosis are screened through 2 sputum smear examinations. Sputum microscopic examination is done in designated RNTCP microscopy centres. They are located either in the CHC, PHC, Taluka Hospitals or in the TB dispensary. Each centre has a skilled technician to ensure quality control, a senior TB laboratory supervisor is appointed for every 5 microscopy centres. The senior TB laboratory supervisor rechecks all the positive slides and 10 per cent of the negative slides of these five microscopy centres. Thus the error in diagnosing a patient is minimized. It is essential to examine 2 sputum specimens of each patient before a conclusive diagnosis can be made. One sputum sample is not sufficient for diagnosis as the chance of detecting smear positive case is only 80 per cent. Sputum microscopy not only confirms the diagnosis, but also indicates the degree of infectivity and response to treatment. Fig. 1 on page number 202 shows the criteria of diagnosis and initiation of treatment.

All patients are provided short-course chemotherapy free of charge. During the intensive phase of chemotherapy all the drugs are administered under direct supervision called Direct Observed Therapy Short-term (DOTS). DOTS is a community based tuberculosis treatment and care strategy which combines the benefits of supervised treatment, and the benefits of community based care and support. It ensures high cure rates through its three components: appropriate medical treatment, supervision and motivation by a health or non-health worker, and monitoring of disease status by the health services. DOTS is given by peripheral health staff such as MPWs, or through voluntary workers such as teachers, anganwadi workers, dais, ex-patients, social workers etc. They are ‘known as DOT ‘Agent’ and paid incentive/honorarium of Rs 150 per patient completing the treatment.

Newer initiatives (20)

1. **Daily regimen for paediatric TB**: In order to transition the country to the updated guidelines for paediatric treatment in the STCI, which follow the current WHO dosing guidelines, the government has decided to introduce a daily dosing regimen using child-friendly fixed dosage combinations (FDCs). The procurement of anti-TB drugs in daily fixed dose combination (FDC) has been initiated. Treatment with FDCs of anti-Tb drugs will be in six weight bands for paediatric patients. An option for family members to provide Directly Observed Treatment (DOT) to paediatric patients has been incorporated in the guidelines.

2. Daily regimen for all forms of TB in the country.
3. Pilots for universal access to TB cases
4. Bedaquiline conditional access programme.
5. Campaign mode — Active case finding: To reach the unreached, the programme has carried out systematic active TB screening among high risk populations through house visits or targeted setting visit (tribal population, slums, old age homes, prisons, orphanages, transit camps etc.) The campaign was conducted in priority districts selected based on burden of TB, case finding efforts, HIV-TB and drug resistant TB in the respective districts (7).

The drugs are supplied in patient-wise boxes containing the full course of treatment, and packaged in blister packs. For the intensive phase, each blister pack contains one day’s medication. For the continuation phase, each blister pack contains one week’s supply of medication. The combipack for extension of intensive phase are supplied separately. The boxes are coloured according to the category of the regimen, red for category I patients, blue for category II patients.

Paediatric tuberculosis

Please refer to page 211 for details.

Drug resistance surveillance (DRS) under RNTCP (16)

The prevalence of drug resistance to TB can be taken as an indicator of the effectiveness of the TB control activities over a period of time and, therefore, RNTCP has taken steps to measure this important indicator.

The aim of DRS is to determine the prevalence of antimycobacterial drug resistance among new sputum smear positive pulmonary tuberculosis (PTB) patients, and also amongst previously treated sputum smear positive PTB patients. Drug-resistant TB has frequently been encountered in India, and its presence has been known virtually from the time anti-TB drugs were introduced for the treatment of TB.

To obtain a more precise estimate of Multi-Drug Resistant TB (MDR-TB) burden in the country, RNTCP carried out drug resistance surveillance (DRS) surveys in accordance with global guidelines in selected states. The results of these surveys indicate prevalence of MDR-TB to be about 2.8 per cent in new cases and 11.60 per cent in retreatment cases (18).

**MANAGEMENT OF DRUG RESISTANT TB**

The services for quality diagnosis and treatment of drug resistant TB cases were initiated in 2007 in Gujarat and Maharashtra. These services since then have been scaled up and currently these services are available across the country from March 2013. For full details about the patient regimens, please refer to page 205.

State-level structure and responsibilities (22)

While a national expert technical working group has developed national policies, technical and operational guidelines, the state-level is where the majority of planning activities, implementation and monitoring occur. The state PMDT Committee is responsible for developing the plan of action for implementation, expansion, maintenance, supervision, monitoring and quality enhancement of PMDT services in the respective state.

Drug-resistant tuberculosis centre (22)

Programmatic and clinical management of DR-TB is complex but feasible when the health system is strengthened to effectively integrate what is necessary. Treatment of drug-resistant TB is not completely based on centralized and institutionalized care for the entire duration. In fact, clinical care needs the presence of a clinical and patient support expert resource centre. This is the DR-TB Centre, which is a 20–30 bedded tertiary care facility established to serve a population of approximately 10 million, with an airborne infection control compliant ward, facilities for pretreatment evaluations, treatment initiations, follow-up monitoring and management of adverse drug reactions, prevention and relief of physical and social suffering caused by the disease and its treatment, complications and co-morbidities. All these activities are supported by the programme staff in addition to having counselling for patients and undertaking data management.
By 2017, 147 DR-TBCs were established across India, designated as Nodal DR-TB centre, one for approximately every 10 million population, including some in private institutes partnering with RNTCP. About 5 to 10 districts are attached to each centre. DR-TB patients are admitted for a short period and once stabilized on treatment, discharged with advance intimation to the districts and referred back to their districts for continuation and completion of treatment. During treatment they are referred back to DR-TBCs for change of regimens and management of adverse reactions.

To decentralize the pretreatment evaluation, treatment initiation of RR-TB or H mono/poly DR-TB and follow-up processes, two different types of DR-TBCs will be established. The existing nodal DR-TB centre (NDR-TBC) will continue for approximately 10 million population. One District DR-TB centre (DDR-TBC) will be established for every district. Some of the states have already established these centres.

The advantages of decentralized “test and treat approach” are (22):

- Early and faster initiation of treatment of all diagnosed DR-TB patients;
- Bringing care closer to the residence of majority of the DR-TB patients;
- Significant reduction in catastrophic expenditure including loss of work hours and family income;
- Rationally minimizing the need and duration for hospitalization;
- Minimizing travel of patients, thereby transmission risks during travels;
- Accountability of the district programme management units; and
- Rationalizing utilization of existing DR-TBCs to enable them to concentrate in more complex clinical decisions and ensuring quality assurance of treatment and research.

1. District DR-TB centre (22)

The DDR-TBC is responsible for the initiation and management of uncomplicated DR-TB patients like RR-TB or H mono/poly DR-TB in a district, not only on inpatient basis, but also on outpatient basis, wherever advisable and possible. The DDR-TBC can be established at institutes in a certain order of preference, namely, medical colleges, district hospitals, TB hospitals and NGO/private/corporate institutes/other sector hospitals with the availability of required clinical expertise.

2. Nodal DR-TB centre (22)

Patients with additional resistance to second-line drugs, drug intolerance, contraindications, failing regimen, patients returning after treatment interruption of >1 month, emergence of any exclusion criteria for standard regimen for RR-TB or H mono/poly DR-TB regimen, non-TB mycobacterium (NTMs) and those needing palliative care would be managed at NDR-TBC.

The requirements for the NDR-TB centre are as follows:

- Should preferably be a tertiary care institute;
- Separate ward for male and female patients should be available with at least 10 beds in each;
- All PMDT services (beds, investigations, ECG and ancillary drugs for management of adverse drug reactions) to be provided free of cost to the patient;
- Relevant specialties including respiratory medicine, general medicine, psychiatry, dermatology, ENT, ophthalmology, gynaecology, paediatrician, anaesthesiologist and cardiologist should be available directly or through linkages;
- NDR-TBC committee to be formed;
- National training of NDR-TBC committee members (including Chairperson);
- National AIC guidelines to be implemented in DR-TB wards and outpatients setting.
- Routine clinical laboratory investigation facility to be made available for pretreatment evaluation and monitoring;
- Ancillary drugs should be available;
- Management of adverse drug reaction as per PMDT guidelines;
- Doctors, nursing and support staff should be available from the institute;
- Reports and records to be maintained for PMDT; and
- Quarterly report to be submitted electronically.

The overall structure and roles of different level of PMDT services are summarized in Fig. 4

TB care services in the private sector

The private sector is everything outside the ambit of the Government run public health services. It varies widely in its size, nature of service delivery and the socio-economic groups served. It holds a factual predominance of health care service delivery in India. As per National Sample Survey Organization report, about 70 per cent patients seek care in private clinics and hospitals (17).

Delays in diagnosis, over-diagnosis of TB due to an over-dependence on X-rays, the use of multiple non-standard regimens for inappropriate durations, the lack of a mechanism to ensure full course of treatment and to record treatment outcomes are some issues of concern in the private sector. Similar problems in varying degrees are encountered in other health sectors as well. The advantages and disadvantages of public and private sector are as shown below:

Source: (17)
The strategic vision of RNTCP is to lay down guidelines and norms for TB care in India. The underlying principle is for RNTCP to extend public services to privately managed patients. Standards for TB care in India, mandatory TB notification, NIKSHAY, ban on serodiagnostics are among the tools to improve TB care services in private sector. Regulatory tools, however, are limited and partnership is preferred. Programme staff should understand that RNTCP needs private providers more than private providers need the RNTCP.

**TB-HIV coordination (23)**

Since the advent of the collaborative efforts in 2001, TB-HIV activities have evolved to cover most of the recommendations as per the latest WHO policy statement issued in 2012. In 2007, the first national framework for joint TB-HIV collaborative activities was developed which endorsed a differential strategy reflective of the heterogeneity of TB-HIV epidemic. Coordinated TB-HIV interventions were implemented including establishment of a coordinating body at national and state level, dedicated human resources, integration of surveillance, joint monitoring and evaluation, capacity building and operational research.

The implementation of collaborative TB-HIV activities are as follows:

1. Intensified TB case finding has been implemented nationwide at all HIV testing centres (known as integrated counselling and testing centres, or ICTCs), and has now been extended to all ART centres.
2. HIV testing of TB patients is now routine through provider initiated testing and counselling (PITC), implemented in all states with the intensified TB-HIV package.
3. Persons found to be HIV-positive are eligible for free HIV care at a network of antiretroviral treatment (ART) centres. ART centres are located in medical colleges, mainly staffed and operated by the state AIDS control societies, and a few are situated within the facilities of private or NGO partners. As of December 2017, there were 536 ART centres operating in the country, 1120 link-ART centres and 158 link-ART plus centres. Ten Regional Centres of Excellence provide second-line ART services for PLHIV, and 24 centres provide second line ART (ART-plus centres). HIV-infected TB patients who are on protease inhibitor based second line ART are getting rifabutin-based TB treatment in place of Rifampicin.
4. Policy decision has been taken by National Technical Working Group on TB/HIV collaborative activities (NTWG on TB/HIV) to expand coverage of whole blood finger prick HIV screening test at all DMC without a stand-alone or F-ICTC.
5. Provider initiated HIV testing and counselling (PITC) among presumptive TB cases (TB suspects) is now a policy—
   a. In high HIV prevalent states/settings - The implementation will be done in a phased manner, starting with high prevalent states and then in A and B category districts in rest of the country.
   b. In low HIV prevalent states/settings - HIV testing among presumptive TB cases should be routinely implemented in the age-group of 25-54 years in low HIV prevalent districts (C & D) at places where there are co-located TB and HIV testing facilities.
6. Intensified case finding activities to be specifically monitored among HIV infected pregnant women and children living with HIV.
7. The National AIDS Control Programme (NACP) and RNTCP have taken the policy decision to adopt isoniazid prophylaxis therapy (IPT) as a strategy for prevention of TB among PLHIV. The implementation will be in a phased manner.
8. The RNTCP has prioritized presumptive TB cases among people living with HIV for diagnosis of TB and Rifampicin resistance with rapid diagnostic tools having high sensitivity e.g. Xpert MTB/RIF. The treatment guidelines are discussed in detail on page 218.
Tuberculosis in pregnancy

Please refer to page 212 for details.

National Strategic Plan (2017–2025) for TB Elimination

The National Strategic Plan (NSP) 2017–2025 for TB elimination builds on the success of last NSP. It is a three year costed plan and an eight year strategic document. It provides goals and strategies for the country’s response to the disease during the period 2017–2025 to bring about significant changes in the incidence, prevalence and mortality of TB, and attain the global End TB targets five years ahead of Sustainable Development Goal of TB free India. The VISION is – TB free India with zero deaths, disease and poverty due to TB (18).

Objectives:

The main objectives of NSP are:

1. Find all drug sensitive TB and drug resistant TB cases with an emphasis on reaching TB patients seeking care from private providers, and undiagnosed TB in high-risk populations.
2. Initiate and sustain all patients on appropriate anti-TB treatment wherever they seek care, with patient friendly systems and social support.
3. Prevent the emergence of TB in susceptible populations.
4. Build and strengthen enabling policies, empowered institutions, additional human resources with enhanced capacities, and provide adequate financial resources.

The key strategies are as follows:

1. Private sector engagement
2. Active case finding
3. Drug resistant TB case management
4. Addressing social determinants including nutrition
5. Robust surveillance system
6. Community engagement and multi-sectoral approach

Expected outcome:

The aim of the National Strategic Plan is to achieve elimination of TB by 2025. During plan period, targets for TB are:

1. 80% reduction in TB incidence (i.e. reduction from 211 per lakh to 43 per lakh)
2. 90% reduction in TB mortality (i.e. reduction from 32 per lakh to 3 per lakh)
3. 0% patient having catastrophic expenditure due to TB

New comprehensively deployed interventions are required to accelerate the rate of decline of incidence of TB to more than 10–15 per cent annually. The requirements of moving towards TB elimination have been integrated into four strategic pillars of Detect-Treat-Prevent-Build (DTPB).

By taking the DTPB approach, the national programme can achieve significant positive change and make a real difference in the lives of many people it serves.

Table 4 highlights the core impact, outcome indicators and targets of the NSP. The four priority areas include private sector engagement, ensuring a seamless efficient TB care cascade, active TB case-finding among key population (socially vulnerable and clinically high risk), and preventing progression from latent TB infection (LTBI) to active TB in high risk groups.

Financial resources

The programme is being assisted by the World Bank and the Department for International Development (DFID) via WHO. In addition, the RNTCP is supported by the Global TB Drug Facility (GDF), Global Fund to Fight AIDS, Tuberculosis and Malaria (GFATM), the United States Agency for International Development (USAID) and DANIDA. Government of India provides 100 per cent grant-in-aid to the implementing agencies i.e., states/UTs, besides free drugs. The states are expected to use the existing infrastructure and also to provide some manpower resources.

NATIONAL AIDS CONTROL PROGRAMME

National AIDS Control Programme was launched in India in the year 1987. The Ministry of Health and Family Welfare has set up National AIDS Control Organization (NACO) as a separate wing to implement and closely monitor the various components of the programme. The aim of the programme is to prevent further transmission of HIV, to decrease morbidity and mortality associated with HIV infection and to minimize the socio-economic impact resulting from HIV infection.

The milestones of the programme are summarized as follows (24):

1986 – First case of HIV detected.
- AIDS Task Force set up by the ICMR.
- National AIDS Committee established under the Ministry of Health.
1990 – Medium Term Plan launched for four states and the four metros.
1992 – NACP-I launched to slow down the spread of HIV infection.
- National AIDS Control Board constituted.
- NACO set-up.
1999 – NACP-II begins, focussing on behaviour change, increased decentralization and NGO involvement.
- State AIDS Control Societies established.
2004 – Anti-retroviral treatment Initiated.
2006 – National Council on AIDS constituted under chairmanship of the Prime Minister.
- National Policy on Paediatric ART formulated.
2017 – National Strategic Plan for HIV/AIDS and STIs 2017–2024

The national strategy has the following components:
- Establishment of surveillance centres to cover the whole country; identification of high-risk group and screening; issuing specific guidelines for management of detected cases and their follow-up; formulating guidelines for blood bank, blood product manufacturers, blood donors and dialysis units; information, education, and communication activities by involving mass media and research for reduction of personal and social impact of the disease; control of sexually transmitted diseases; and condom programme.

The package of services under NACP-IV are as follows (25):

1. Prevention services
- Targeted interventions for high-risk groups (female sex workers, men who have sex with men, transgenders, hijras, injecting drug users) and bridge population (truckers and migrants).
- Needle-syringe exchange programme and opioid substitution therapy for IDUs.
- Prevention interventions for migrant population at source, transit and destination.
- Link worker scheme for HRGs and vulnerable population in rural areas.
- Prevention and control of sexually transmitted infections/reproductive tract infections.
- Blood safety.
- HIV counselling and testing services.
- Prevention of parent to child transmission.
- Condom promotion.
- Information, education and communication and behaviour change communication (BCC). 
- Social mobilization, youth interventions and adolescence education programme.
- Mainstreaming HIV/AIDS response.
- Work place interventions.

2. Care, support and treatment services
- Laboratory services for CD4 testing and other investigations.
- Free first-line and second-line Anti-Retroviral Therapy (ART) through ART centres and Link ART Centres (LACs), Centres of Excellence (CoE) and ART plus centres.
- Paediatric ART for children.
- Early infant diagnosis for HIV exposed infants and children below 18 months.
- Nutritional and psycho-social support through Care and Support Centres (CSC).
- HIV/TB coordination (cross-referral, detection and treatment of co-infections).
- Treatment of opportunistic infections.
- Drop-in centres for PLHIV networks.

Organizational structure

The National AIDS Control Organization (NACO) is presently established as a division under the Ministry of Health and Family Welfare, headed by the Additional Secretary, Ministry of Health and Director General, NACO Govt. of India. The technical divisions are headed by officers at the level of Deputy Director General/DGHS. The finance division is headed by Director-Finance while Admin and Procurement is headed by the Joint Secretary, Ministry of Health. Fig. 5 shows the NACO structure.
Country scenario

Based on sentinel surveillance data, the HIV prevalence in adult population can be broadly classified into three groups of States/UTs in the country.

Group I: High Prevalence States: includes states of Maharashtra, Tamil Nadu, Karnataka, Andhra Pradesh, Manipur and Nagaland where the HIV infection has crossed 5 per cent mark in high-risk group and 1% or more in antenatal women.

Group II: Moderate Prevalence States: includes states of Gujarat, Goa and Puducherry where HIV infection has crossed 5% or more among high risk groups but the infection is below 1% in antenatal women.

Group III: Low Prevalence States: includes remaining states where the HIV infection in any of the high risk groups is still less than 5% and is less than 1% among antenatal women.

Categories of Districts

In the country, the districts have been classified according to the epidemiological and vulnerability-criteria using the sentinel surveillance data for the last 3 years (Table 5).

Accordingly, 156 districts have been classified as category A, 39 districts as category B, 296 as category C and 118 as category D districts. The planning for HIV related services has also been graded as per categorization of districts. This approach has been implemented since March 2007.

HIV surveillance

Different types of surveillance activities are being carried out in the country to detect the spread of the disease and to make appropriate strategy for prevention and control viz., area specific targeted intervention and best practice approach. The types of surveillance are: (a) HIV Sentinel Surveillance, (b) HIV Sero-Surveillance, (c) AIDS Case Surveillance, (d) STD Surveillance, (e) Behavioural Surveillance, and (f) Integration with surveillance of other diseases like tuberculosis etc.

HIV SENTINEL SURVEILLANCE: After the establishment of the fact that HIV infection is present in wide geographic areas, the aim of surveillance was redefined to monitor the trends of HIV infection. The objectives of the surveillance are as follows (28):

1. To determine the level of HIV infection among general population as well as high-risk groups in different states;
2. To understand the trends of HIV epidemic among general population as well as high-risk groups in different states;
3. To understand the geographical spread of HIV infection and to identify emerging pockets;
4. To provide information for prioritization of programme resources and evaluation of programme impact; and
5. To estimate HIV prevalence and HIV burden in the country.

The objective of the surveillance is best achieved by annual cross-sectional survey of the risk group, in the same place over few years by unlinked anonymous serological testing procedures by two ERS (i.e., when HIV testing is carried out without indentityfication of name of samples collected for other purposes e.g., VDRL in STD clinics. The objective of surveillance may be fulfilled in this example whereas the positive person is not identified). The number of samples to be screened must represent the risk group under study and the sample size is determined accordingly. Clinical based approach for such collection has many advantages including the procedure for collection of samples which should be carried out on the above lines to avoid “selection bias” and “participation bias”

PTCT = Parent to child transmission

Source: (27)
To start with, the HIV sentinel surveillance for HIV was taken up from 1994 in 55 sentinel sites attached to the existing surveillance centres and were increased to 180 in 1998. While the number of the high risk groups of HIV sentinel sites were increased every year, with change of sites, these 180 sites have remained consistent. Inclusion of data from high-risk population through targeted intervention sites and the additional sub-set of rural samples through antenatal clinics are the key features of HIV sentinel surveillance. Pregnant women attending antenatal clinics are taken as proxy for general population. The number of HIV sentinel surveillance sites for different population groups during 2016-17 are as shown in Table 6.

The strategy adopted for collection and testing of samples during HIV Sentinel Surveillance Round 2016-2017 was as follows (Table 7).

Counselling and HIV testing services

The Basic Service Division of the department of AIDS control provides HIV counselling and testing services for HIV infection. The national programme is offering these services since 1997 with the goal to identify as many people living with HIV as early as possible (after acquiring the HIV infection), and linking them appropriately and in a timely manner to prevention, care and treatment services. The introduction of ART services for people living with HIV/AIDS in 2004, gave a major boost to counselling and testing services in India. The HIV counselling and testing services include the following components:

1. Integrated Counselling and Testing Centres (ICTC).
3. HIV/tuberculosis collaborative activities.

INTEGRATED COUNSELLING AND TESTING CENTRES

Diverse models of HIV counselling and testing services are available to increase access to HIV diagnosis, these include testing services in health care facilities, standalone sites and community-based approaches at various levels of public health systems in India from state, district, sub-district and village/community levels as depicted in Fig. 6.

Types of facilities for HIV counselling and testing services

Integrated Counselling and Testing Centres (ICTC): A person is counselled and tested for HIV at ICTC, either of his own free will (client initiated) or as advised by a medical provider (provider initiated). Functions of ICTC include early detection of HIV, provision of basic information on modes of transmission and prevention of HIV/AIDS for promoting behavioral change and reducing vulnerability, and linking PLHIV with other HIV prevention, care and treatment services. The ICTC have been classified into two types: Fixed facility ICTC and Mobile ICTC.

1. Fixed facility ICTCs are located within an existing health facility/hospital/health centre, and are of two types – Standalone ICTC and Facility-integrated counselling and testing centres.
   a. Standalone ICTC (SA-ICTC): The client load is high in these centres, with full-time counsellor and laboratory technician who provide HIV counselling and testing services. SA-ICTC are located in medical colleges, district hospitals, sub-district hospitals, CHCs etc.
   b. Facility-integrated counselling and testing centres (F-ICTC): Considering the need for rapid scale-up and sustainability of HIV counselling and testing services, the F-ICTCs have been set up below the block levels at 24 x 7 PHC, etc. Staff of the existing health facilities are trained in counselling and testing services of HIV. The HIV service delivery is ensured with logistic support from DAC. Similar to F-ICTC at 24 x 7 PHC, the Public Private Partnership (PPP)-ICTCs were established in private facilities (for profit/not-for-profit hospitals, laboratories, non-governmental organizations etc.), and have been supported by DAC/SACs in supply of rapid HIV testing kits, training of existing staff, quality assurance, supply of protective kits and prophylactic drugs for post-exposure prophylaxis for staff, supply of IEC materials such as flip charts, posters etc. required for ICTC.

2. Mobile ICTC: Mobile counselling and testing centre is a van with a room to conduct general examination, counselling and space for collection and processing blood samples by a team of paramedical healthcare providers (a health educator/ANM, counsellor and laboratory technician). Mobile ICTC are set up as temporary clinics in hard-to-reach areas with flexible working hours and provide a wide range of services like counselling and testing services for HIV, syndromic management of STI/RTI and other minor ailments, along with regular health check-ups, antenatal, immunization services etc.

Community based HIV screening: In order to offer HIV testing to every pregnant woman in the country, so as to detect all HIV positive pregnant women and eliminate transmission of HIV from parent to child, the community based HIV screening is conducted by frontline health workers (Auxiliary Nurse Midwives) at the sub-centre level.

PREVENTION OF PARENT-TO-CHILD TRANSMISSION OF HIV

The prevention of parent-to-child transmission of HIV/AIDS (PPTCT) programme was started in the country in the year 2002. Currently there are more than 15,000 ICTCs in the country which offer PPTCT services to pregnant women. The aim of the PPTCT programme is to offer HIV testing to every pregnant woman (universal coverage) in the country, so as to cover all estimated HIV positive pregnant women and eliminate transmission of HIV from mother-to-child.

In India, PPTCT interventions under NACP was started in 2002, using SD-NVP prophylaxis for HIV positive pregnant women during labour and also for her new born child immediately after birth. With the department of AIDS control adopting “Option B” of the World Health Organization recommendations (2010), India has also transitioned from the single dose Nevirapine strategy to that of multi-drug ARV prophylaxis from September 2012. This strategy was executed in the three southern high HIV prevalence states of Andhra Pradesh, Karnataka and Tamil Nadu. The national strategic plan for PPTCT services using multi-drug ARVs in India was developed in May-June 2013 for nationwide implementation in a phased manner. Based on the new WHO guidelines (June 2013) and on the suggestions from the technical resource groups during December 2013, department of AIDS control has decided to initiate lifelong ART (using the triple drug regimens) for all pregnant and breast-feeding women living with HIV, regardless of CD4 count or WHO clinical stage, both for their own health and to prevent vertical HIV transmission, and for additional HIV prevention benefits.

The PPTCT services provide access to all pregnant women for HIV diagnostic, prevention, care and treatment services. As such, the key goal is to ensure the integrated PPTCT service delivery with the existing Reproductive and Child Health (RCH) programme.

The essential package of PPTCT services in India are as follows (30):

1. Routine offer of HIV counselling and testing to all pregnant women enrolled into antenatal care, with an ‘opt out’ option.
2. Ensuring involvement of spouse and other family members, and move from an “ANC-Centric” to a “Family-Centric” approach.
3. Provision of life-long ART (TDF+3TC+EFV) to all pregnant and breast-feeding HIV infected women, regardless of CD4 count and clinical stage of HIV progression.
4. Promotion of institutional deliveries of all HIV infected pregnant women.
5. Provision of care for associated conditions (STI/RTI, TB and other opportunistic infections).
6. Provision of nutrition, counselling and psychosocial support for HIV infected pregnant women.
7. Provision of counselling and support for initiation of exclusive breast-feeds within an hour of delivery as the preferred option and continued for 6 months.
8. Provision of ARV prophylaxis to infants from birth upto a minimum of 6 months.
9. Integrating follow-up of HIV-exposed infants into routine healthcare services including immunization.
10. Ensuring initiation of Co-trimoxazole Prophylactic Therapy (CPT) and Early Infant Diagnosis (EID) using HIV-DNA PCR at 6 weeks of age onwards, as per the EID guidelines.
11. Strengthening community follow-up and outreach through local community networks to support HIV-positive pregnant women and their families.

HIV TESTING OF TB PATIENTS

Detection of HIV by offering HIV tests to diagnosed TB patients is being implemented by NACP and RNTCP jointly
since 2007-08. States with high HIV prevalence cover about 90% TB patients for HIV testing, but case fatality rate among HIV infected TB cases remains 13-14%, as compared to less than 4% in HIV negative TB cases, indicating delayed detection of HIV/TB inspite of good coverage. Therefore, NACP and RNTCP have jointly decided to offer HIV testing upstream during evaluation of patients for TB when they present with TB symptoms. This activity is expected to expedite detection of HIV within 2-4 weeks of TB positivity, leading to early linkage to HIV treatment and hence reduction in mortality. HIV testing in presumptive TB cases was rolled-out in India in October 2012 in Karnataka, followed by Maharashtra, Andhra Pradesh and Tamil Nadu. It is planned to extend this strategy to high HIV prevalence districts i.e. A and B category districts. Further the NTWG has recommended implementation of this strategy among 25-54 years age group in the rest of the country.

The four pronged strategy for HIV-TB coordination activity to reduce mortality are summarized in Fig. 7.

Care, support and treatment

The care, support and treatment (CST) component of NACP aims to provide comprehensive services to people living with HIV (PLHIV) to improve the survival and quality of life. The policy package includes the following (7):

- Free universal access to life long standardized antiretroviral therapy (ART);
- Free laboratory diagnostic and monitoring services (baseline tests, CD4 testing, targeted viral load);
- Facilitating long term retention in care;
- Prevention, diagnosis and management of opportunistic infection; and
- Linkage to care and support services and linkage to social protection scheme.

The country has adopted fast track target of 90-90-90 which aims at ending AIDS as public health threat by 2030 by achieving fast track targets by 2020. They are as follows:

1. 90 per cent of PLHIV know their status, of which
2. 90 per cent of PLHIV are on ART, of which
3. 90 per cent of PLHIV have viral suppression.

A significant step of rolling out “test and treat” policy has been taken towards achieving these targets.

CST services are provided through ART centres established by DAC in health facilities across the country. These are linked to Centres of Excellence (CoE) and ART-Plus centres at selected institutions, while some of the services have been decentralized through Link ART Centres (LAC). ART centres are also linked to ICTCs, STI clinics, PPTCT services and other clinical departments in the institutions of their location, as well as with the Revised National Tuberculosis Programme (RNTCP), in order to ensure proper management of TB-HIV co-infected patients. Fig. 8 gives a graphic view of this service delivery model.
As of March 2017, about 530 ART centres, 1108 link ART centres, 17 centres of excellence, 7 paediatric centres of excellence, 52 ART Plus centres and 350 care and support centres are functioning in the country (7).

**Services provided**

1. **First-line ART:** First-line ART is provided free of cost to all eligible PLHIV through ART centres. Positive cases referred by ICTCs are registered in ART centres for pre-ART and ART services. The assessment for eligibility for ART is done through clinical examination and CD4 count. Patients are also provided counselling on treatment adherence, nutrition, positive prevention and positive living. Follow-up of patients on ART is done by assessing drug adherence, regularity of visits, periodic examination and CD4 count (every six months). Treatment for opportunistic infections is also provided through ART centres. Till August 2017, 11.33 lakh PLHIV were on first-line ART.

2. **Alternative first-line ART:** It has been observed that a small number of patients initiated on first-line ART experience acute/chronic toxicity/intolerance to first-line ARV drugs, thus necessitating change of ARV drugs to alternative first-line drugs. Presently, the provision of alternative first-line ART is done through the Centres of Excellence and ART-Plus centres across the country.

3. **Second-line ART:** The second-line ART began in January 2008 at two sites — GHTM, Tambaram, Chennai and JJ Hospital, Mumbai on a pilot basis, and was then further expanded to the other CoEs in January 2009. Further decentralization of second-line ART was done through capacitating and upgrading some well-functioning ART centres as 'ART-Plus Centres'. Till March 2014, 8,897 patients were receiving second-line drugs at CoEs and ART-Plus centres. All ART centres are linked to CoE/ART-Plus centres. For the evaluation of patients for initiation on second-line and alternate first-line ART, a State AIDS Clinical Expert Panel (SACEP) has been constituted by DAC at all CoEs and ART-Plus centres. This panel meets once a week for taking decisions on patients referred to them with treatment failure/major side effects.

4. **Third-line ART:** Some patients on second-line ART also experience treatment failure. National programme rolled out third-line regimen for them in 2015. Currently, Raltegravir and Darunavir are used for third-line regimen (7).

**National paediatric HIV/AIDS Initiative:** The national paediatric HIV/AIDS initiative was launched on 30 November 2006. Till March 2014, nearly 1.06,824 children living with HIV/AIDS (CLHIV) were registered in HIV care at ART centres, of whom 42,015 were receiving free ART. Paediatric formulations of ARV drugs are available at all ART centres.

**Paediatric second-line ART:** While the first-line therapy is efficacious, certain proportion of children do show evidence of failure. There is not much data available on the failure rate of Nevirapine-based ART in children. However, WHO estimates that the average switch rate from first to second-line ART is 2–3% per year for adults. It is likely that similar rates are applicable for children as well. Currently, second-line ART for children has been made available at all CoE and ART-Plus centres.

**Early infant diagnosis:** In order to promote confirmatory diagnosis for HIV exposed children, a programme on Early Infant Diagnosis (EID) was launched by DAC. All children with HIV infection confirmed through EID have been linked to ART services.

**Follow up and monitoring:** Patients initiated on ART are regularly followed up on monthly basis. The basic examination including weight measurement, clinical evaluation, and screening for opportunistic infections is done on every visit. Assessment of adherence is done by counsellor on every visit and necessary support is provided as per requirement. CD4 testing is done every six months to monitor the response of ART. During each visit, patients are encouraged to visit care and support centers for psychosocial support and availing various social beneficiary scheme (7).

**Management of Opportunistic infection (7):** Screening prophylaxis and management of various opportunistic infections is an important part of comprehensive HIV care. Following intervention are done at ART centers for this:

a. **HIV-TB:** TB is the most common opportunistic infection among PLHIVs. All patients attending ART centers including new registrations, pre-ART and on ART patients are screened verbally for 4 symptom complex. In case any one of the symptom is present, patients are referred for TB testing. Those diagnosed with co-infection are initiated on Anti TB treatment from ART center followed by ART. When TB is ruled out, Isoniazide prophylaxis is offered. NACP works in close coordination with RNTCP for managing co-infections.

b. **HIV-Hepatitis B and Hepatitis C:** The PLHIV are at high risk of co-morbidity with hepatitis B and C. It is important to ensure timely detection and initiation of Hepatitis B or C treatment in HIV/hepatitis co-infected patients to minimize hepatitis-related liver disease and its long-term negative impact on HIV outcomes. Hepatitis B and C detection and treatment for PLHIV will be provided at ART centers. Hepatitis B treatment is available as part of ART programme since ART regimens containing tenofovir (TDF) plus a second NRTI active against HBV (3TC/FTC) have been shown to suppress both HIV and HBV viral replication. Treatment for Hepatitis C needs direct acting antivirals (DAAs) such as sofosbuvir, grazoprevir, glecaprevir etc. (26).

c. **HIV - Kala-azar:** Kala-azar or Visceral Leishmaniasis is endemic in some districts of states like UP, Bihar and Jharkhand. All PLHIVs with symptoms suggestive of Kala-azar are screened for Kala-azar and those found infected are referred for appropriate treatment.

d. **Other opportunistic infection:** PLHIVs are regularly screened for co-infection and co-morbidities. Those diagnosed having these are referred for appropriate treatment.

**TARGETED INTERVENTIONS FOR HIGH RISK GROUPS:** The main objective of targeted interventions (TI) is to improve health-seeking behaviour of high-risk groups (HRG) and reduce their risk of acquiring sexually transmitted infections (STI) and HIV infections. High risk groups under TI include female sex workers (FSW), men who have sex with men (MSM), transgenders (TG)/ hijras and injecting drug users (IDU), and bridge populations include high risk behaviour migrants and long distance truckers. Targeted interventions provide the information,
means and skills needed to prevent HIV transmission and improve their access to care, support and treatment services. These programmes also focus on improving sexual and reproductive health and general health of high-risk population.

The services offered through targeted interventions include:
- Detection and treatment for sexually transmitted infections.
- Condom distribution (except in TI for bridge population).
- Condom promotion through social marketing (for HRG and bridge population).
- Behaviour change communication.
- Creating an enabling environment with community involvement and participation.
- Linkages to integrated counselling and testing centres.
- Linkages with care and support services for HIV positive HRGs.
- Community organization and ownership building
- Specific interventions for IDUs.
  - Distribution of clean needles and syringes.
  - Abscess prevention and management.
  - Opioid substitution therapy
  - Linkage with detoxification/rehabilitation services.
- Specific Interventions for MSM/TGs.
  - Provision of lubricants.
  - Specific Interventions for TG/hijra populations
  - Provision of project-based STI clinics.

**Link worker scheme:** The Link worker scheme is a community-based outreach strategy to address HIV prevention and care needs of HRG and vulnerable population in rural areas. The specific objectives of the scheme include reaching out to these groups with information and knowledge on prevention and risk reduction of HIV and STI, condom promotion and distribution, providing referral and follow-up linkages for various services. It includes counselling, testing and treatment of STI and opportunistic infections through link workers, creating an enabling environment for PLHIV and their families, and reducing stigma and discrimination against them. In partnership with various development partners, the link worker scheme has been expanded and is being implemented in 18 states covering 163 highly vulnerable districts.

**Blood transfusion services:** The division of blood safety has been renamed as the division of blood transfusion services. The change in nomenclature is to broaden the horizon of blood safety to include transfusion transmitted infections, immuno-hematology, quality management systems, logistics and other processes involved to improve confidence in the "safe blood".

Blood transfusion services have been considered as an integral part of the health care system. Blood Transfusion Councils have been set-up at national and state levels. Professional blood donation has been prohibited in the country since 1st January 1998. Only licensed blood banks are permitted to operate in the country and voluntary blood donation is encouraged. The strategy is to ensure safe collection, processing, storage and distribution of blood and blood products. Zonal blood testing centres have been established to provide linkage with other blood banks affiliated to public, private and voluntary sectors. As per national blood safety policy, testing of every unit of blood is mandatory for detecting infections like HIV, hepatitis B, hepatitis C, malaria and syphilis.

Access to safe blood for the needy is the primary responsibility of NACO. It is supporting a network of 1,131 blood banks, including 590 Blood Component Separation Units (BCSU) and 34 Model Blood Banks, 108 major blood banks and 591 district level blood banks (7). NACO supported the installation of BCSU and has given funds for modernization of all major blood banks at state and district levels. Besides enhancing awareness about the need to procure safe blood and blood products, NACO has supported the procurement of equipment, test kits and reagents, and is helping in the recurring expenditure of government blood banks and those run by voluntary/charitable organizations, that were modernized.

In order to ease the situation of shortage of availability of blood in the rural areas, where it is not feasible to operate a blood bank, Govt. has decided to establish blood storage centres at First Referral Units (FRUs), at sub-district levels, for wider availability of safe blood, particularly for emergency obstetric care and trauma care services.

**Condom promotion:** Condom promotion strategies will be strengthened through free distribution and social marketing channels, non-traditional outlets, female condoms, etc. aided by an effective communication strategy. The programme will continue to link prevention with care, support and treatment. This will promote positive prevention.

On the basis of HIV prevalence and family planning needs, the districts have been mapped and classified into four categories: (a) High prevalence of HIV and high fertility (HPHF); (b) High prevalence of HIV and low fertility (HPLF); (c) Low prevalence of HIV and low fertility (LPLF); and (d) Low prevalence of HIV and high fertility (LPHF). During 2014 the coverage of condom social marketing programme implementation was spread across 395 districts, i.e. 141 HPHF, 384 HPLF and 170 LPHF districts in 11 states (29).

**STD CONTROL PROGRAMME** : STD control is linked to HIV/AIDS control as behaviour resulting in the transmission of STD and HIV are same. HIV is transmitted more easily in the presence of another STD. Hence, early diagnosis and treatment of STD is now recognized as one of the major strategies to control spread of HIV infection. The following approach is adopted for the STD control (33):

a. Management of STDs through syndromic approach (management of sexually transmitted diseases based on specific symptoms and signs and not dependent on laboratory investigations). Please refer to page 360 chapter 5 for details.

b. STDs among women, though highly prevalent, are suppressed because of the social stigma attached to the disease. It has, therefore, been decided to integrate services for treatment of reproductive tract infections (RTIs) and sexually transmitted diseases (STDs) at all levels of health care. Department of Family Welfare and NACO will coordinate their activities for an effective implementation of such integration. STDs Clinics at district / block/ First Referral Unit (FRU) level would function as referral centres for treatment of STDs referred from peripheries. STDs clinics in all district hospitals, medical colleges and other centres would be...
strengthened by providing technical support, equipment, reagents and drugs. A massive orientation-training programme would be undertaken to train all the medical and paramedical workers engaged in providing STIs services through a syndromic approach. All STIs clinics would also provide counselling services and good quality condoms to the STI patients. Services of NGOs would be utilised for providing such counselling services at the STIs clinics.

NACO has branded the STI/RTI services as "Suraksha Clinic", and has developed a communication strategy for generating demand for these services (3).

**PRE-PACKED STI/RTI COLOUR CODED KITS :** Pre-packed colour coded STI/RTI kits have been provided for free supply to all designated STI/RTI clinics. These kits are being procured centrally and supplied to all State AIDS Control Societies.

The colour code is as follows (34):

- Kit 1 — grey, for urethral discharge, ano-rectal discharge and cervicitis.
- Kit 2 — green, for vaginitis.
- Kit 3 — white, for genital ulcers.
- Kit 4 — blue, for genital ulcers.
- Kit 5 — red, for genital ulcers.
- Kit 6 — yellow, for lower abdominal pain.
- Kit 7 — black, for inguinal bubo.

**National Strategic Plan for HIV/AIDS and STI 2017-2024 (26)**

The National Strategic Plan for HIV/AIDS and STI (2017-2024) is developed with a vision of an AIDS free India. The mission is to attain universal coverage of HIV prevention, testing, treatment to care continuum that is effective, inclusive, equitable and adapted to population and local needs.

**Goal:** The goal is to achieve zero new infection, zero AIDS-related deaths and zero AIDS related stigma and discrimination.

**Strategic framework:** The NSP is designed around a results-based framework that reflects the fast-track targets and the 'ending of AIDS' commitment. The framework is based on a causal relationship between the vision, mission, goal and the outcomes. This will be articulated in terms of inputs, outputs and costs in the implementation plan. While there are several external and internal risks that may positively or adversely affect results, the combination of strategies adopted will be calibrated according to the epidemiological, health priorities and resource scenarios of different State/UTs and in cognisance of needs of people living with HIV and the communities.

Based on this strategic framework, a specific planning approach is required which helps differentiate States and Union Territories (UT) according to three predominant epidemiological contexts (26):

(i) States/UT with a 'mature' epidemic where HIV incidence and prevalence are high in key, bridge and other at-risk populations and, in some cases, in other segments of the general population.

(ii) Those States/UT where there are 'emerging' epidemics with relatively new and rising rates of infection among key, bridge and other at-risk populations.

(iii) States/UT with 'low' or stable epidemics where there is still a need to focus on potential risks among key, bridge and other at-risk populations, to maintain the low infection rates and eliminate HIV transmission.

While a range of services is needed in all the three case scenarios, the mix and relative weight of each set of interventions and service-delivery models may need to vary accordingly. The most critical interventions include prevention, outreach, testing and counselling, treatment, PPTCT, viral load suppression, care and support, as well as social protection. Programmatic support components (e.g. monitoring and evaluation, surveillance, research, laboratory services, procurement etc.) remain relevant across all three contexts. However, the service delivery modality, the level of integration into health systems and corresponding budget requirements will vary according to the epidemiological, social and demographic characteristics of the above three contexts.

**Objectives:** This NSP proposes six objectives towards fulfilling its vision of an AIDS free India. These are:

- **Objective 1:** Reduce 80% new infections by 2024 (Baseline 2010)
- **Objective 2:** Ensure 95% of estimated PLHIV know their status by 2024
- **Objective 3:** Ensure 95% PLHIV have ART initiation and retention by 2024, for sustained viral suppression
- **Objective 4:** Eliminate mother-to-child transmission of HIV and syphilis by 2020.
- **Objective 5:** Eliminate HIV/AIDS related stigma and discrimination by 2020
- **Objective 6:** Facilitate sustainable NACP service delivery by 2024

Achievement of these objectives by 2024 would result in the following (26):

1. Estimated new infections will reduce from 102,226 (2010) to < 21,000 per year
2. 2.14 million PLHIV of the total estimated PLHIV (2.25 million) would know their status
3. 2.03 million PLHIV would be put on ART
4. 1.93 million PLHIV would be retained on treatment and have HIV VL < 1000 copies/ml
5. Attainment of < 50 cases of new paediatric HIV infections per 100,000 live births with a mother-to-child transmission rate < 5% by 2020 and maintenance of same thereof
6. Attainment of < 50 cases of new congenital syphilis per 100,000 live births and maintenance of same thereof
7. HIV/AIDS will be perceived as chronic manageable disease with no stigma and discrimination attached to it.
8. Key components of the NACP such as prevention outreach, testing, treatment, prevention of mother-to-child transmission, viral load suppression, care and support, as well as social protection schemes will continue through 100% domestic funding.

**Information, education and communication**

Communication is the key to generating awareness on prevention as well as motivating access to testing, treatment, care and support. Communication in NACP-IV is directed at:

a. To increase knowledge among general population (especially youth and women) on safe sexual behaviour;
b. To sustain behaviour change in high risk groups and bridge populations;
c. To generate demand for care, support and treatment services; and
d. To make appropriate changes in societal norms that reinforce positive attitude, beliefs and practices to reduce stigma and discrimination.

Adolescence Education Programme: This programme runs in secondary and senior secondary schools to build up life skills of adolescents to cope with the physical and psychological changes associated with growing up. Under the programme, 16 hour sessions are scheduled during the academic terms of class IX and XI. State AIDS control society have further adapted the modules after state level consultations with NGOs, academicians, psychologists and parent-teacher bodies. This programme is being implemented in 23 states and by March 2014, 49,000 schools have been covered.

Red Ribbon Clubs: The purpose of Red Ribbon Club formation in colleges is to encourage peer-to-peer messaging on HIV prevention and to provide a safe space for young people to seek clarifications of their doubts and myths surrounding HIV/AIDS. The RRCs also promote voluntary blood donation among youth.

NATIONAL PROGRAMME FOR CONTROL OF BLINDNESS

The National Programme for Control of Blindness was launched in the year 1976 as a 100 per cent centrally sponsored programme and incorporates the earlier trachoma control programme started in the year 1968. The programme was launched with the goal to reduce the prevalence of blindness from 1.4 to 0.3 per cent. As per 2006–07 survey the prevalence of blindness was 1.0 per cent (1).

Main objectives of the programme in the 12th Five Year Plan period are:
1. To continue three ongoing signature activities, i.e., performance of 66 lacs cataract operations per year; school eye screening and distribution of 9 lacs free spectacles per year to school children suffering from refractive errors; and collection of 50,000 donated eyes per year for keratoplasty (6).
2. To reduce the backlog of avoidable blindness through identification and treatment of curable blind at primary, secondary and tertiary levels, based on assessment of the overall burden of visual impairment in the country;
3. Develop and strengthen the strategy of NPCB for “Eye Health for All” and prevention of visual impairment, through provision of comprehensive universal eye-care services and quality service delivery;
4. Strengthening and upgradation of Regional Institutes of Ophthalmology (RIOs) to become centre of excellence in various sub-specialties of ophthalmology and also other partners like Medical Colleges, District Hospitals, Sub-district Hospitals, Vision Centres, NGO Eye Hospitals;
5. Strengthening the existing infrastructure facilities and developing additional human resources for providing high quality comprehensive eye care in all districts of the country;
6. To enhance community awareness on eye care and lay stress on preventive measures;
7. Increase and expand research for prevention of blindness and visual impairment; and
8. To secure participation of voluntary organizations/private practitioners in delivering eye care.

Salient features/strategies adopted to achieve the objectives are:
1. Continued emphasis on free cataract surgery through the health care delivery system as well as by the involvement of NGO sector and private practitioners.
2. Emphasis on the comprehensive eye care programmes by covering diseases other than cataract, like diabetic retinopathy, glaucoma, corneal transplantation, vitreoretinal surgery, treatment of childhood blindness etc. These emerging diseases need immediate attention to eliminate avoidable blindness from the country.
3. Reduction in the backlog of blind persons by active screening of population above 50 years age, organizing screening eye camps and transporting operable cases to fixed eye care facilities.
4. Refractive error comprises a major part of avoidable blindness. Screening of children for identification and treatment of refractive errors and provision of free glasses to those affected and belonging to poor socio-economic strata.
5. Coverage of underserved area for eye care services through public-private partnership.
6. Capacity building of health personnel for improving their knowledge and skill in delivery of high quality eye services
7. Information Education Communication (IEC) activities for creating awareness on eye-care within the community.
8. Regional Institutes of Ophthalmology and Medical Colleges of the states to be strengthened in a phased manner with latest equipments and training of manpower so that they can be upgraded as Centres of Excellence in the regions.
9. The district hospitals to be strengthened by upgrading infrastructure, equipment and providing adequate manpower like ophthalmologists and PMOAs on contractual basis and provide earmarked funds for basic medicines and drugs.
10. Continuing emphasis on primary healthcare (eye care) by establishing vision centres in all PHCs with a PMOA in position.
11. Multipurpose District Mobile Ophthalmic Units for better coverage.

To avoid duplicity of work, State Ophthalmic Cell has been merged with State Blindness Control Society, and after the launch of NRHM, State Blindness Control Societies have been further merged with State Health Society. Likewise, District Blindness Control Societies have also been merged with District Health Societies. Facilities for intra-ocular lens implantation have been expanded to taluka level.

The problem of blindness is acute in rural areas, and hence the programme has tried to expand the accessibility of eye services in these areas. At present there are 80 central mobile units attached to medical colleges and 341 district mobile units to provide eye care in mobile eye camps. These units have a vehicle, ophthalmic surgeon and other paramedical staff. Most of the cataract surgeries in rural population are conducted through these mobile camps. Primary health centres are the basic units in the rural areas.
The findings of the survey conducted during 2001–2002, in randomly selected districts of the states covered by World Bank Project shows that dependence on eye camps has reduced, except in remote and tribal areas; involvement of PHC/CHC doctor in the programme has increased; higher percentage of cataract operated persons consult the doctor at an early stage; there is an increase in demand for modern techniques like intra-ocular lenses and suture-less surgeries; and about 64 per cent of cataract operated persons receive free spectacles from the health facilities.

The organizational structure for the national programme for control of blindness is as shown in Fig. 9.

**Administration**

- **Central**
  - Ophthalmology Section, Directorate General of Health Services, Ministry of Health & FW, New Delhi

- **State**
  - State Ophthalmic Cell, Directorate of Health Services, State Health Societies

- **District**
  - District Blindness Control Society

**Service Delivery and Referral System**

- **Tertiary Level**
  - Regional Institutes of Ophthalmology & Centres of Excellence in Eye Care Medical Colleges

- **Secondary Level**
  - District Hospital and NGO Eye Hospital

- **Primary Level**
  - Sub-district level hospitals/CHCs
  - Mobile Ophthalmic Units
  - Upgraded PHCs
  - Link Workers/Panchayats

**Organizational structure for national programme for control of blindness**

Source: (35)

**SCHOOL EYE SCREENING PROGRAMME** : 6–7 per cent of children aged 10–14 years have problem with their eye sight affecting their learning at school. Children are being first screened by trained teachers. Children suspected to have refractive error are seen by ophthalmic assistants and corrective spectacles are prescribed or given free for persons below poverty line.

**COLLECTION AND UTILIZATION OF DONATED EYES** : During 2015–16 nearly 24,510 donated eyes were collected for corneal implantation (6). Hospital retrieval programme is the major strategy for collection of donated eyes, which envisage motivation of relatives of terminally ill patients, accident victims and others with grave diseases to donate eyes. Eye donation fortnight is organized from 25th August to 8th September every year to promote eye donation. Eye banking. Gujarat, Tamil Nadu, Maharashtra and Andhra Pradesh are leading states in this activity (1).

The voluntary organizations such as Lions International and its branches, Rotary International and its branches, NSPB India etc. are encouraged to organize eye camps in remote rural and urban areas as per guidelines, with the permission from the state authorities. They have been active in providing eye health education, preventive, rehabilitative and surgical services for control of blindness.

Community health education is a built-in component at all levels of implementation of National Blindness Control Programme. The programme also includes regular eye check-up and provision of vitamin A prophylaxis and service facilities in rural areas.

**WHO assistance for prevention of blindness** : This includes intra-country fellowships in corneal transplantation, vitreo-retinal surgery, lasers in ophthalmology and paediatric ophthalmology; pilot survey on childhood blindness in Delhi; training in district programme management; study on situational analysis of eye care infrastructure and human resources in India; high quality workshops in eye care for faculty of medical colleges; and development of plan of action for “Vision 2020 : The Right to Sight” Initiative.

**Vision 2020 : The Right to Sight**

It is a global initiative to reduce avoidable (preventable and curable) blindness by the year 2020. India is also committed to this initiative. The plan of action for the country has been developed with following main features:

1. Target diseases are cataract, refractive errors, childhood blindness, corneal blindness, glaucoma, diabetic retinopathy.

2. Human resource development as well as infrastructure and technology development at various levels of health system. The proposed four tier structure includes Centres of Excellence (20), Training Centres (200), Service Centres (2000), and Vision Centres (20,000).

**Universal eye health : a global action plan 2014–2019 (36)**

WHO estimates that in 2010 there were 285 million people visually impaired, of which 39 million were blind. If just the
two major causes of visual impairment were considered priorities and control measures were implemented consistently by providing refractive services and offering cataract surgery to the people in need, two-thirds of the visually impaired people could recover good eye sight.

Provision of effective and accessible eye care services is the key to control measures. The preference should be given to strengthening eye care services through their integration into the primary health care and health system development, as almost all causes of visual impairment are avoidable, e.g., diabetes mellitus, smoking, premature birth, rubella, vitamin A deficiency etc., and visual impairment is frequent among older age groups. Improvements in the areas of maternal, child and reproductive health and the provision of safe drinking water and basic sanitation are important. Eye health should be included in the broader non-communicable and communicable disease frameworks, as well as those addressing ageing populations. There are three indicators to measure progress at the national level. They are:

1. The prevalence and causes of visual impairment. As a global target, reduction in prevalence of avoidable visual impairment by 25 per cent by 2019 from the baseline of 2010 has been selected for this action plan;
2. The number of eye care personnel; and
3. Cataract surgical service delivery. The cataract surgical rate (number of surgeries performed per year, per million population) and cataract surgical coverage (number of individuals with bilateral cataract causing visual impairment, who have received cataract surgery on one or both eyes).

**IODINE DEFICIENCY DISORDERS (IDD) PROGRAMME**

India commenced a goitre control programme in 1962, based on iodized salt. At the end of three decades, the prevalence of the disease still remained high.

As a result, a major national programme – “The IDD Control Programme” was initiated in which nation-wide, rather than area-specific use of iodized salt is being promoted. It was decided as a national policy to fortify all edible salt in a phased manner by end of 8th Plan. The essential components of a national IDD programme are use of iodized salt in place of common salt, monitoring and surveillance, manpower training and mass communication.

The objectives of the programme are (1):

1. Surveys to assess the magnitude of the Iodine Deficiency Disorders in districts
2. Supply of iodized salt in place of common salt.
3. Resurveys to assess iodine deficiency disorders and the impact of iodized salt after every 5 years in districts.
4. Laboratory monitoring of iodized salt and urinary iodine excretion.
5. Health education and publicity.

**Significant achievements**

Consequent upon liberalization of iodized salt production, Salt Commissioner has issued licenses to 824 salt manufacturers out of which 777 units have commenced production. These units have an annual production capacity of 222 lakh metric tonnes of iodized salt.

The production/supply of iodized salt from April 2015 to August 2015 was 26.44 lakh tonnes and 25.12 lakh tonnes.

Notification banning the sale of non-iodized salt for different human consumption in the entire country is already issued under “Food Safety & Standards Act 2006 and Regulations 2011”.

For effective implementation of National Iodine Deficiency Disorders Control Programme 34 States/UTs have established Iodine Deficiency Disorders Control Cells in their State Health Directorate.

**UNIVERSAL IMMUNIZATION PROGRAMME**

Experience with smallpox eradication programme showed the world that immunization was the most powerful and cost-effective weapon against vaccine preventable diseases. In 1974, the WHO launched its “Expanded Programme on Immunization” (EPI) against six, most common, preventable childhood diseases, viz. diphtheria, pertussis (whooping cough), tetanus, polio, tuberculosis and measles. From the beginning of the programme UNICEF has been providing significant support to EPI.

“Expanded” in the WHO definition meant adding more disease controlling antigens of vaccination schedules, extending coverage to all corners of a country and spreading services to reach the less privileged sectors of the society (37).

The primary health care concept as enunciated in the 1978 Alma-Ata Declaration included immunization as one of the strategies for reaching the goal of “Health For All” by the year 2000. While the WHO’s programme is called EPI, the UNICEF in 1985 renamed it as “Universal Child Immunization” (UCI). There was absolutely no difference between these two. The goal was the same, i.e., to achieve universal immunization by 1990. EPI is regarded as the instrument of UCI (38).

The first vaccine to be introduced in India was BCG in 1962 as part of the National Tuberculosis Programme. Over the years, various new vaccines have been introduced and many milestones achieved. Table 8 gives a chronological listing of some important milestones in India’s immunization programme.

The Government of India launched its EPI in 1978 with the objective of reducing the mortality and morbidity resulting from vaccine-preventable diseases of childhood, and to achieve self-sufficiency in the production of vaccines. Universal Immunization Programme was started in India in 1985. It has two vital components: immunization of pregnant women against tetanus, and immunization of children in their first year of life against the six EPI target diseases. The aim was to achieve 100 per cent coverage of pregnant women with 2 doses of tetanus toxoid (or a booster dose), and at least 85 per cent coverage of infants with 3 doses each of DPT, OPV, one dose of BCG and one dose of measles vaccine by 1990. Universal immunization was first taken up in 30 selected districts and catchment areas of 50 Medical Colleges in November 1985. The programme now covers entire country and practice areas of all the 242 Medical colleges, thus creating a base for wider coverage (40). A “Technology Mission on Vaccination and Immunization of Vulnerable Population, specially Children” was set up to cover all aspects of the immunization activity from research and development to actual delivery of services to the target population (41).
The immunization services are being provided through the existing health care delivery system (i.e., MCH centres, primary health centres and subcentres, hospitals, dispensaries and ICD units). There is no separate cadre of staff for EPI. The recommended immunization schedule is on page 134.

Although the target was “universal” immunization by 1990, in practice, no country, even in the industrialized world, has ever achieved 100 per cent immunization in children. ‘Universal’ immunization is, therefore, best interpreted as implying the ideal that no child should be denied immunization against tuberculosis, diphtheria, whooping cough, tetanus, polio and measles. It is, however, generally agreed that when immunization coverage reaches a figure of 80 per cent or more, then disease transmission patterns are so severely disrupted as to provide a degree of protection even for the remaining children who have not been immunized, because of “herd immunity” (42). It is also important that children are immunized during the first year of life and that levels of immunization are sustained so that each new generation is protected.

Significant achievements have been made in India. At the beginning of the programme in 1985-86, vaccine coverage ranged between 29 per cent for BCG and 41 per cent for DPT. By the end of 2016, coverage levels had gone up significantly to about 87 per cent for tetanus toxoid for pregnant women, about 89 per cent for BCG, 88 per cent for DPT 3 doses, 88 per cent for measles, 86 per cent for OPV 3 doses, 88 per cent for HepB, 80 per cent for Hib, and 76 per cent for MCV. Since then, there is a significant decline in the reported incidence of the vaccine preventable diseases as compared to their incidence in 1987, as shown in Table 9.

To strengthen routine immunization, Government of India has planned the State Programme Implementation Plan (PIP) part C. It consists of: (a) Support for alternate vaccine delivery from PHC to sub-centre and outreach.
sessions; (b) Deploying retired manpower to carry out immunization activities in urban slums and underserved areas, where services are deficient; (c) Mobility support to district immunization officer as per state plan for monitoring and supportive supervision; (d) Review meeting at the state level with the districts at 6 monthly intervals; (e) Training of ANM, cold chain handlers, mid-level managers, refrigerator mechanics etc.; (f) Support for mobilization of children to immunization session sites by ASHA, women self-help groups etc.; (g) Printing of immunization cards, monitoring sheet, cold chain chart vaccine inventory charts etc.

In addition, central government is supporting in supplies of auto-disable syringes, downsizing the BCG vial from 20 doses to 10 doses to ensure that BCG vaccine is available in all immunization session sites, strengthening and maintenance of the cold chain system in the states, and supply of vaccines and vaccine van.

PULSE POLIO IMMUNIZATION PROGRAMME

Pulse Polio Immunization Programme was launched in the country in the year 1995. Under this programme children under five years of age are given additional oral polio drops in December and January every year on fixed days. From 1999-2000, house to house vaccination of missed children was also introduced. The NIDs rounds cover approximately 172 million children and SNIDs rounds cover 40-80 million children. In addition, large scale multi-district mop-ups have been conducted (43). As a result only one case of polio was reported in 2011 in the month of January. As on 25th Feb 2012, India was removed from the list of polio endemic countries, and on 27th March 2014, India was certified as polio-free country. Please see page 228 for more details.

INTRODUCTION OF INACTIVATED POLIO VACCINE (IPV)

The last global case due to WPV type-2 was reported at Aligarh in India in 1999. Most of the global cases due to VDPVs (97%) as well as VAPP (40%) are due to type-2 virus. This necessitates the discontinuation of the use of type-2 component from OPV. Polio Endgame Strategic Plan thus recommends replacing rOPV with bOPV. However, this puts the recent birth cohort at the time of switch at risk of VDPV and wild polio virus type 2 due to silent/ongoing transmission of VDPV type-2 and also to potential leakage of wild polio virus type-2 in case of accidental/intended leakage of the virus from a laboratory. To mitigate this risk, inactivated polio vaccine was introduced prior to the rOPV-bOPV switch in April 2016. As part of this Polio Endgame Strategy, India has introduced Inactivated Polio Vaccine (IPV) from 30 November 2015. It is given as fractional IPV of 0.1 ml dose as intradermal injection at 6 and 14 weeks of life (6).

INTRODUCTION OF MEASLES VACCINE SECOND OPPORTUNITY

In order to accelerate the reduction of measles related morbidity and mortality, second opportunity for measles vaccination is being implemented. The National Technical Advisory Group on immunization recommended introduction of 2nd dose of measles vaccine to children between 9 months and 10 years of age through supplementary immunization activity (SIA) for states where evaluated coverage of first dose of measles vaccination is less than 80 per cent. In states, with coverage of measles vaccination more than 80 per cent, the second dose of vaccine will be given through routine immunization at 16-24 months (1).

INTRODUCTION OF PENTAVALENT VACCINE (DPT + Hep B + Hib)

The pentavalent vaccine contains five antigens i.e., hepatitis B, diphtheria, pertussis, tetanus and haemophilus influenza b (Hib) vaccine. Pentavalent vaccine is given at 6th, 10th and 14th weeks as primary dose. The vaccine has replaced DPT and hepatitis B vaccines in the immunization schedule. However, birth dose of hepatitis B and two booster doses of DPT will continue as before (6).

Initially, India introduced pentavalent vaccine in two states – Kerala and Tamil Nadu. Presently it covers the whole country.

INTRODUCTION OF JAPANESE ENCEPHALITIS VACCINE

The programme was introduced in 2006 to cover 104 endemic districts in phased manner, using SA 14-14-2 vaccine, imported from China. Single dose of JE vaccine was given to all children between 1 to 15 years of age through campaigns (3). The JE vaccine is being integrated into routine immunization in the districts where campaign had already been conducted to immunize the new cohort of children by vaccinating with two doses at 9-12 months and 16-24 months (1).

21 high burden districts have been identified in Assam, Uttar Pradesh and West Bengal for adult JE vaccination in the age group of 15-65 years. This will cut down deaths and morbidity due to JE in adults as well (6).

INTRODUCTION OF ROTA VIRUS VACCINE

Rota virus vaccine was introduced in 2016 in Odisha, Himachal Pradesh, Haryana and Andhra Pradesh, and later on will be expanded to the whole country. It will be given under universal immunization programme as a 3 dose vaccine along with pentavalent 1st, 2nd and 3rd dose (6).

RUBELLA VACCINE

To be initiated as Measles Rubella (MR) campaign targeting 9 months to 15 years of age in a phased manner over a period of three years. Subsequently, the Rubella vaccine will be introduced as MR vaccine as two doses in the place of measles containing vaccine 1 and 2 at 9-12 months and 16-24 months as per NTAGI recommendations (6).

MISSION INDRADHANUSH

The Ministry of Health & Family Welfare has launched “Mission Indradhanush”, depicting seven colours of the rainbow, in December 2014, to fully immunize 90 per cent of children who are either unvaccinated or partially vaccinated; those that have not been covered during the rounds of routine immunization for various reasons, by 2020. The target has now been pre-poned to 2018 (7).

Mission Indradhanush has completed four phases (from April 2015 to July 2017) covering 528 districts wherein 2.55 crore children were reached; 66.57 Lakh
children were immunized; and 68.79 lakh pregnant women were immunized. The first two phases of Mission Indradhanush have led to an increase of 6.7 per cent in full immunization coverage in one year, as compared to 1 per cent in the past. This increase was more in rural areas (7.9 per cent) as compared to urban areas (3.1 per cent), hence shifting the focus of the programme towards urban areas (7).

Intensified Mission Indradhanush: A total of 190 districts/urban areas across 24 states have been identified where intensified mission indradhanush has started. It was launched in Oct 2017. It involves intensive preparation, implementation and integration of sessions into regular immunization microplans. The focus is an urban slum areas and districts with slowest progress and completion of due-list of beneficiaries on the basis of head count surveys. As on 15th Jan, 2018, number of children vaccinated were 49.30 lakh; number of children fully vaccinated was 12.02 lakh; and number of pregnant women vaccinated was 10.05 lakh (7).

MEASLES–RUBELLA (MR) VACCINE

The WHO regional goal for SEAR is measles elimination and rubella/congenital rubella syndrome control by 2020. The MR vaccine is being introduced through campaign, targeting around 41 crore children in the age group of 9 months to 15 years in phased manner (covering 1.3rd of the total population of the country), followed by 2 doses in routine immunization at 9–12 months and 16–24 months replacing the measles vaccine (7).

MR campaign was launched in February 2017 from 5 States/UTs (Karnataka, Tamil Nadu, Goa, Lakshadweep and Puducherry) where 3.34 crore children were vaccinated against the target of 3.43 crore, with a coverage of 97 per cent. The next-phase started for 8 States/UTs from August, 2017. The States/UTs covered were Andhra Pradesh, Chandigarh, Daman & Diu, Dadra & Nagar Haveli, Telangana, Kerala, Himachal Pradesh and Uttarakhland, where around 3.21 crore children were vaccinated by December 2017. The remaining states/UTs are planned for MR campaign subsequently (7).

PNEUMOCOCCAL VACCINE (PCV)

PCV was launched in May 2017 for reducing infant mortality and morbidity caused by pneumococcal pneumonia. The vaccine has been introduced in Himachal Pradesh, 6 districts of Uttar Pradesh and 17 districts of Bihar (7).

Very frequently queries come up about the vaccines and the vaccination schedule. It is important to have the exact answer to these questions

Questions about all vaccines (44)

Q. If the mother/caregiver permits administration of only one injection during an infant’s first visit at 9 months of age, which vaccine should be given?
A. DPT or OPV with Vitamin-A

Q. Which vaccines can be given to a child between 1–5 years of age, who has never been vaccinated?
A. The child should be given DPT1, OPV-1, measles and 2 ml of vitamin A solution. It should then be given the second and third doses of DPT and OPV at one month intervals. Measles second dose is also to be given as per the schedule. The booster dose of OPV/DPT can be given at a minimum of 6 months after administering OPV3/DPT3.

Q. Which vaccines can be given to a child between 5–7 years of age, who has never been vaccinated?
A. The child should be given first, second and third doses of DPT at one month intervals. The booster dose of DPT can be given at a minimum of 6 months after administering DPT3 upt to 7 years of age.

Q. Should one re-start with the first dose of a vaccine if a child is brought late for a dose?
A. Do not start the schedule all over again even if the child is brought late for a dose. Pick up where the schedule was left off.

Q. What should one do if the child is found allergic to DPT or develops encephalopathy after DPT?
A. As pertussis cases were reported in higher age group children and the risk of AEFI’s were not found to be more after DPT vaccine as compared to DT vaccine.
Q. Why give the measles vaccine only on the right upper arm?
A. The measles vaccine is given on the right upper arm to maintain uniformity and to help surveyors in verifying the receipt of the vaccine.

Q. If a child has received the measles vaccine before 9 months of age, is it necessary to repeat the vaccine later?
A. Yes, the measles vaccine needs to be administered, according to the National Immunization Schedule i.e. after the completion of 9 months until 12 months of age and at 16-24 months. If not administered in the ideal age for measles vaccine, it can be administered up to 5 years of age.

Q. What is measles catch-up campaign?
A. A measles catch-up campaign is a special campaign to vaccinate all children in a wide age group in a state or a district with one dose of measles vaccine. The catch-up campaign dose is given to all children, both immunized and un-immunized, who belong to the target age group of 9 months to 10 years. The goal of a catch-up campaign is to quickly make the population immune from measles and reduce deaths from measles. A catch-up campaign must immunize nearly 100% of target age group children.

Q. Why is BCG given only upto one year of age?
A. Most children acquire natural clinical/sub-clinical tuberculosis infection by the age of one year. This too protects against severe forms of childhood tuberculosis e.g. TB meningitis and miliary disease.

Q. Why is BCG given only on the left upper arm?
A. BCG is given on the left upper arm to maintain uniformity and for helping surveyors in verifying the receipt of the vaccine.

Q. Why give birth dose of hepatitis B vaccine only within 24 hours of birth?
A. The birth dose of Hepatitis B vaccine is effective in preventing perinatal transmission of Hepatitis B if given within the first 24 hours.

Q. Up to what age can hepatitis B vaccine be given?
A. According to the National Immunization Schedule, Hepatitis B vaccine should be given with the first, second and third doses of DPT till one year of age.

Q. Why do we give 0.05 ml dose of BCG to newborns (below 1 month of age)?
A. This is because the skin of newborns is thin and an intra-dermal injection of 0.1 ml may break the skin or penetrate into the deeper tissue and cause local abscess and enlarged axillary lymph nodes. Dose of 0.05 ml is sufficient to elicit adequate protection.

Q. Why is OPV given to children till 5 years of age?
A. OPV can be given to children till 5 years of age.

Q. Can OPV and vitamin A be given together with DPT-booster dose?
A. Yes.

Q. Can an infant be breast-fed immediately after OPV?
A. Yes.

Q. If a child has received all doses of DPT and TT as per the NIS till 16 years of age and she gets pregnant at 20 years, should she get one dose of TT during pregnancy?
A. Give 2 doses of TT during the pregnancy as per the schedule.

Q. If a child above 2 years (24 months) of age has not received the JE vaccine through either RI or an SIA, should she/he be given the JE vaccine?
A. Yes, the child is eligible to receive a dose of the JE vaccine, through RI, till the age of 15 years.

Following are some Do’s and Don’ts during immunization sessions (44):

**BCG vaccine**

Q. Why give BCG vaccine only on the left upper arm?
A. BCG is given on the left upper arm to maintain uniformity and for helping surveyors in verifying the receipt of the vaccine.

Q. Why do we give 0.05 ml dose of BCG to newborns (below 1 month of age)?
A. This is because the skin of newborns is thin and an intra-dermal injection of 0.1 ml may break the skin or penetrate into the deeper tissue and cause local abscess and enlarged axillary lymph nodes. Dose of 0.05 ml is sufficient to elicit adequate protection.
### Do's and Don’ts during immunization sessions

#### Vaccination schedule
- It is safe and effective to give BCG, DPT, OPV, and Measles vaccines at the same time to a child who has completed 9 months and never been vaccinated.
- Give BCG to infants less than 1 year of age (never give BCG to children above 1 year of age).
- If a child is brought late for a dose, pick up where the schedule was left off. For example, if a child left with DPT-2 and comes after 3 months give DPT-3.

#### Cold chain
- Check expiry date and VVM label of vaccine vial before immunizing every child.
- Keep the vaccines and diluents in a plastic bag/zipper bag in the centre of vaccine carrier with 4 conditioned ice-packs. Make sure that the diluents are also at +2 to +8 centigrade before reconstitution.
- Take one ice pack from vaccine carrier and keep reconstituted BCG & Measles vaccines only on the top of the ice pack.

#### Vaccine handling and administration
- Welcome beneficiaries.
- Wash hands before conducting the session.
- Verify beneficiary's record and age of the child.
- Screen for contraindications.
- Check label of the vial and expiry date.
- Lightly shake the vial of T-Series Vaccine before drawing the dose.
- Use a new AD syringe for each injection and new disposable syringe for each reconstitution.
- Use correct site and route for vaccination.
- Give appropriate vaccine.
- Inject vaccine using the correct site and route for the vaccine e.g. Intradermal in left arm for BCG; subcutaneous in right arm for Measles; intramuscular in anterolateral aspect of mid thigh for DPT and Hepatitis B.
- Allow dose to self-disperse instead of massaging.
- Explain potential adverse events following immunization and what to do.
- Discuss with beneficiaries/parents about next visit.

#### Recording and reporting
- Fully document each immunization in the immunization card, tally sheet, and immunization register. Ask parents/guardians to bring the card on next visit.
- Retain the counterfoil.

#### Adverse events following immunization (AEFI)
- In case of serious AEFI refer the patient to appropriate health facility.
- Inform your supervisor immediately – document the type of vaccine(s), batch number, expiry date, and full address of the child.
- Report all serious AEFIs to the MOH.

#### Social mobilization
- Use vaccination card to remind parents when to return with their child.
- Enlist community team like AWW, ASHA, NGOs and other community-based workers to remind parents of the importance of full immunization.

---

### NATIONAL HEALTH MISSION

The Ministry of Health and Family Welfare is implementing various schemes and programmes and national initiatives to provide universal access to quality health care. The approach is to increase access to the decentralized health system by establishing new infrastructure in deficient areas and by upgrading the infrastructure in existing institutions. As part of the plan process, many different programmes have been brought together under the overarching umbrella of National Health Mission (NHM), with National Rural Health Mission (NRHM) and National Urban Health Mission (NUHM) as its two sub-Missions. The National Health Mission was approved in May 2013. The main programmatic components include health system strengthening in rural and urban areas; Reproductive – Maternal – Newborn – Child and Adolescent Health (RMNCH+A); and control of communicable and non-communicable diseases. An important achievement of NHM
has been considerable reduction in out of pocket expenses from 72 per cent to 60 per cent (1).

The Government of India has introduced a series of programmes over the past two decades to address maternal and newborn health. The major milestones so far include (45):

- a. 1992 – Child Survival and Safe Motherhood Programme (CSSM)
- b. 1997 – RCH I
- c. 2005 – RCH II
- d. 2005 – National Rural Health Mission
- e. 2013 – RMNCH+A Strategy
- f. 2013 – National Health Mission
- g. 2014 – India Newborn Action Plan (INAP)

Under NHM, health interventions/initiatives are regularly designed and implemented to address the healthcare needs of the country. A list of interventions currently being implemented under NHM to reduce IMR and MMR is given below (46):

- Promotion of institutional deliveries through Janani Suraksha Yojana.
- Capacity building of health care providers in basic and comprehensive obstetric care.
- Operationalization of sub-centres, primary health centres, community health centres and district hospitals for providing 24 x 7 basic and comprehensive obstetric care services.
- Name based web enabled tracking of pregnant women to ensure antenatal, intranatal and postnatal care.
- Mother and child protection card in collaboration with the Ministry of Women and Child Development to monitor service delivery for mothers and children.
- Antenatal, intranatal and postnatal care including iron and folic acid supplementation to pregnant & lactating women for prevention and treatment of anaemia.
- Village health and nutrition days in rural areas as an outreach activity, for provision of maternal and child health services.
- Health and nutrition education to promote dietary diversification, inclusion of iron and foliate rich food as well as food items that promote iron absorption.
- Janani Shishu Suraksha Karyakram (JSSK) entitles all pregnant women delivering in public health institutions to absolutely free and no expense delivery including caesarean section. The initiative stipulates free drugs, diagnostics, blood and diet, besides free transport from home to institution, between facilities in case of a referral, and drop back home. Similar entitlements have been put in place for all sick infants accessing public health institutions for treatment.
- To sharpen the focus on the low performing districts, 184 high priority districts have been prioritized for Reproductive Maternal Newborn Child Health + Adolescent (RMNCH+A) interventions for achieving improved maternal and child health outcomes.
- Emphasis on facility based newborn care at different levels to reduce child morbidity and mortality: Setting up of facilities for care of sick newborn such as Special New Born Care Units (SNCUs). Newborn Stabilization Units (NBSUs) and Newborn Care Corners (NBCCs) at different levels is a thrust area under NHM.

Capacity building of health care providers: Various trainings are being conducted under NHM to train doctors, nurses and ANMs for essential newborn care, early diagnosis and case management of common ailments of children. These trainings are on Navjaat Shishu Suraksha Karyakram (NSSK), Integrated Management of Neonatal and Childhood Illnesses (IMNCI), Facility Based Newborn Care (FBNC), Infant and Young Child Feeding practices (IYCF), etc.

- India Newborn Action Plan (INAP) has been launched with an aim to reduce neonatal mortality and stillbirths.
- Newer interventions to reduce newborn mortality - vitamin K injection at birth, antenatal corticosteroids for preterm labour, kangaroo mother care and injection gentamicin to young infants in cases of suspected sepsis.
- Home Based New Born Care (HBNC): Home based newborn care through ASHAs has been initiated to improve new born practices at the community level and early detection and referral of sick new born babies.

Intensified Diarrhoea Control Fortnight (IDCF) to be observed in July-August focusing on ORS and Zinc distribution for management of diarrhoea and feeding practices.

Integrated Action Plan for Pneumonia and Diarrhoea (IAPPD) launched in four states with highest infant mortality (Uttar Pradesh, Madhya Pradesh, Bihar and Rajasthan).

- Management of malnutrition: Nutritional Rehabilitation Centres (NRCs) have been established for management of severe acute malnutrition in children.

- Appropriate infant and young child feeding practices are being promoted in convergence with Ministry of Woman and Child Development.

- Universal Immunization Programme (UIP): Vaccination protects children against many life threatening diseases such as tuberculosis, diphtheria, pertussis, polio, tetanus, hepatitis B, Hib, measles and Japanese encephalitis in endemic districts. Infants are thus immunized against nine vaccine preventable diseases every year. The Government of India supports the vaccine programme by supply of vaccines and syrings, cold chain equipment and provision of operational costs.

- Mission Indradhanush has been launched in 528 high focus districts to reach more than 2.5 crore children who are either unvaccinated or partially vaccinated; those that have not been covered during the rounds of routine immunization for various reasons. They will be fully immunized against eight life-threatening but vaccine preventable diseases which include diphtheria, whooping cough, tetanus, polio, tuberculosis, measles, haemophilus influenza type B and hepatitis-B. In addition, vaccination against Japanese encephalitis will be provided in selected districts/states of the country. Pregnant women will also be immunized against tetanus.

- Mother and Child Tracking System (MCTS): A name based mother and child tracking system has been put in place which is web based to ensure registration and tracking of all pregnant women and new born babies so that provision of regular and complete services to them can be ensured.
HEALTH PROGRAMMES IN INDIA

- Rashtriya Bal Swasthya Karyakram (RBSK) for health screening and early intervention services has been launched to provide comprehensive care to all the children in the age group of 0-18 years in the community. The purpose of these services is to improve the overall quality of life of children through early detection of birth defects, diseases, deficiencies, development delays including disability.

- Under National Iron Plus Initiative (NIPI), through life cycle approach, age and dose specific IFA supplementation programme is being implemented for the prevention of anaemia among the vulnerable age groups like under-5 children, children of 6-10 years of age group, adolescents, pregnant and lactating women and women in reproductive age along with treatment of anaemic children and pregnant mothers at health facilities.

The targets and achievements of National Health Mission

The targets and achievements of National Health Mission are as shown in Table 10.

### NATIONAL URBAN HEALTH MISSION

NUHM seeks to improve the health status of the urban population particularly slum dwellers and other vulnerable section by facilitating their access to quality health care. NUHM would cover all state capitals, district headquarters and about 779 other cities/towns with a population of 50,000 and above (as per census 2011) in a phased manner. Cities and towns below 50,000 population will be covered by NRHM. The NUHM will focus on (37):

1. Urban poor population living in listed and unlisted slums;
2. All other vulnerable population such as homeless, rag-pickers, street children, rickshaw pullers, construction and brick and lime-kiln workers, sex workers and other temporary migrants;
3. Public health thrust on sanitation, clean drinking water, vector control etc.; and
4. Strengthening public health capacity of urban local bodies.

The treatment of seven metropolitan cities, viz., Mumbai, New Delhi, Chennai, Kolkata, Hyderabad, Bengaluru and Ahmedabad will be different. These cities are expected to manage NUHM through their Municipal Corporation directly.

The NUHM will provide flexibility to the states to choose which model suits the needs and capacities of the states to best address the healthcare needs of the urban poor. Models will be decided through community-led action. All the services delivered under the urban health delivery system through the urban PHCs and urban CHCs will be universal in nature, whereas the outreach services will be targeted to the target group (slum dwellers and other vulnerable groups). Outreach services will be provided through the Female Health Workers (FWHs), essentially ANMs with an induction training of three to six months, who will be placed at the Urban PHCs. These ANMs will report at the U-PHC and then move to their respective areas for outreach services on designated days. On other days, they will conduct immunization and ANC clinics etc. at the U-PHC itself.

The NUHM would encourage the effective participation of the community in planning and management of health care services. It would promote a community health volunteer - Accredited Social Health Activist (ASHA) or Link Worker (LW) in urban poor settlement (one ASHA for 1000-2500 urban poor population covering about 200 to 500 households); ensure the participation by creation of community-based institutions like Mahila Arogya Samiti (MAS) (50-100 households) and Rogi Kalyan Samitis. However, the states will have the flexibility to either engage ASHA or entrust her responsibilities to MAS. In that case, the incentives accruing to ASHA would accrue to MAS (47). The NUHM would provide annual grant of Rs. 5000/- to MAS every year.

Essential services to be rendered by the ASHA may be as follows (47):

(i) Active promoter of good health practices and enjoying community support.
(ii) Facilitate awareness on essential RCH services, sexuality, gender equality, age at marriage/pregnancy; motivation on contraception adoption, medical termination of pregnancy, sterilization, spacing methods. Early registration of pregnancies, pregnancy care, clean and safe delivery, nutritional care during pregnancy, etc.

Source: (7, 46)
pregnancy, identification of danger signs during pregnancy, counselling on immunization, ANC, PNC etc., act as a depot holder for essential provisions like oral re-hydration therapy (ORS), Iron Folic Acid Tablet (IFA), chloroquine, oral pills and condoms, etc.; identification of target beneficiaries and support the ANM in conducting regular monthly outreach sessions and tracking service coverage.

(iii) Facilitate access to health related services available at the Anganwadi/Primary Urban Health Centres/Urban Local Body (ULBs) and other services being provided by the ULB/State/Central Government.

(iv) Formation and promotion of Mahila Arogya Samitis in her community.

(v) Arrange escort/accompany pregnant women and children requiring treatment to the nearest Urban Primary Health Centre, secondary/tertiary level health care facility.

(vi) Reinforcement of community action for immunization, prevention of water borne and other communicable diseases like TB (DOTS), Malaria, Chikungunya and Japanese Encephalitis.

(vii) Carrying out preventive and promotive health activities with AWW/Mahila Arogya Samiti.

(viii) Maintenance of necessary information and records about births and deaths, immunization, antenatal services in her assigned locality as also about any unusual health problem or disease outbreak in the slum, and share it with the ANM in charge of the area.

In return for the services rendered, she would receive a performance based incentive. For this purpose a revolving fund would be kept with the ANM at the U-PHC (in the PHC account), which would be replenished from time to time.

The urban health care facilities are as shown in Fig. 11.

**Urban Primary Health Centre**

Functional for a population of around approximately 50,000-60,000, the U-PHC may be located preferably within a slum or near a slum within half a kilometer radius, catering to a slum population of approximately 25,000-30,000, with provision for OPD. The cities, based upon the local situation, may establish a U-PHC for 75,000 for areas with very high density and can also establish one for around 5,000-10,000, slum population for isolated slum clusters.

At the U-PHC level services provided will include OPD (consultation), basic laboratory diagnosis, drug/contraceptive dispensing, apart from distribution of health education material delivering RCH services and counselling for all communicable and non-communicable diseases. In order to ensure access to the urban slum population at convenient timings, the U-PHC may provide services from 12 noon to 8 pm. It will not include in-patient care. The staff pattern will be as shown in Fig. 11.

**Referral unit**

Urban Community Health Centre (U-CHC) may be set up as a satellite hospital for every 4-5 U-PHCs. The U-CHC would cater to a population of 2,50,000. It would provide in-patient services and would be a 30-50 bedded facility. U-CHCs would be set up in cities with a population of above 5 lakhs, wherever required. These facilities would be in addition to the existing facilities (SDH, DH) to cater to the urban population in the locality.

Health Systems

4. Number of ANMs recruited *
5. No. of Special Outreach health camps organized in the slum/HFAs *
6. No. of UHNDs organized in the slums and vulnerable areas. *
7. Number of UPHCs made operational. *
8. Number of UCHCs made operational. *
9. No. of RKS created at UPHC and UCHC. *
10. OPD attendance in the UPHCs.
11. No. of deliveries conducted in public health facilities.

RCH Services

12. ANC early registration in first trimester.
13. Number of women who had ANC check-up in their first trimester of pregnancy
14. TT (2nd dose) coverage among pregnant women.
15. No of children fully immunized through public health setting
16. No. of severely Acute Malnourished (SAM), child referred and referred for treatment

Communicable Diseases

17. No. of malaria cases detected through blood examination.
18. No. of TB cases identified through chest symptomatic.
19. No. of suspected TB cases referred for sputum examination.
20. No. of MDR-TB cases put under DOTS-plus.

Non-communicable Diseases

21. No. of diabetes cases screened in the city.
22. No. of cancer cases screened in the city.
23. No. of hypertension cases screened in the city.

* Year 2013–14 being the baseline year, the indicators for these NUHM components would be zero. For other indicators, the figure for 2012–13 will be the base line.

Source: (47)

Impact level targets of NUHM are as follows:

1. Reduce IMR by 40% (in urban areas) – National Urban IMR down to 20 per 1000 live births by 2017.
2. Reduce MMR by 50%.
3. Achieve universal access to reproductive health including 100% institutional delivery.
4. Achieve replacement level fertility (TFR 2.1).
5. Achieve all targets of disease control programmes

NATIONAL RURAL HEALTH MISSION

Recognizing the importance of health in the process of economic and social development and to improve the quality of life of its citizens, the government of India launched "National Rural Health Mission" (NRHM) on 5th April, 2005 for a period of 7 years (2005–2012) and recently extended upto year 2017. The mission seeks to improve rural health care delivery system. It is operational in the whole country with special focus on 18 states viz. 8 Empowered Action Group states (Bihar, Jharkhand, Madhya Pradesh, Chattisgarh, Uttar Pradesh, Uttarakhand, Orissa and Rajasthan), 8 North East states (Assam, Arunachal Pradesh, Manipur, Meghalaya, Mizoram, Nagaland, Sikkim and Tripura), Himachal Pradesh and Jammu and Kashmir. By making necessary changes in the basic health care delivery system the mission adopts a synergic approach by relating health to determinants of good health viz. of nutrition, sanitation, hygiene and safe drinking water. It also brings the Indian system of medicine (AYUSH) to the mainstream of health care (9).

The main aim of NRHM is to provide accessible, affordable, accountable, effective and reliable primary health care, and bridging the gap in rural health care through creation of a cadre of Accredited Social Health Activist (ASHA). The mission is an instrument to integrate multiple vertical programmes along with their funds at the district level. The programmes integrated into NRHM are existing programmes of health and family welfare including RCH II; national vector borne disease control programmes against malaria, filaria, kala-azar, dengue fever/DHF and Japanese encephalitis; national leprosy eradication programme; revised national tuberculosis control programme; national programme for control of blindness; iodine deficiency disorder control programme, and integrated disease surveillance project (9).

PLAN OF ACTION TO STRENGTHEN INFRASTRUCTURE

1. Creation of a cadre of Accredited Social Health Activist (ASHA).
2. Strengthening sub-centres by: (a) Supply of essential drugs both allopathic and AYUSH to the sub-centre; (b) Provision of multipurpose worker (male)/additional ANMs wherever needed; sanction of new sub-centres and upgrading existing sub-centres; and (c) Strengthening sub-centres with unified funds of Rs. 10,000 per annum in all 18 states.
3. Strengthening Primary Health Centres: Mission aims at strengthening PHCs for quality preventive, promotive, curative, supervisory and outreach services through (a) Adequate and regular supply of essential drugs and equipment to PHCs (including supply of auto-disabled syringes for immunization); (b) Provision of 24 hours service in at least 50 per cent PHCs by including an AYUSH practitioner; (c) Following standard treatment guidelines; (d) Upgradation of all the PHCs for 24 hours referral service and provision of second doctor at PHC level (one male and one female) on the basis of felt need; strengthening the ongoing communicable disease control programmes and new programmes for control of non-communicable diseases.
4. Strengthening Community Health Centres for First Referral care by (a) Operating all existing CHCs (30–50 beds) as 24 hours first referral units, including
posting of an anaesthetist; (b) Codification of new “Indian Public Health Standards” (Refer to chapter 20 for more details) by setting up norms for infrastructure, staff, equipment, management etc. for CHCs; (c) Promotion of “Rogi Kalyan Samiti” for hospital management; and (d) Developing standards of services and costs in hospital care.

The NRHM infrastructure is as shown in Fig. 12.

District is the core unit of planning, budgeting and implementation of the programme. All vertical health and family welfare programmes at district level have merged into one common “District Health Mission” and at state level into “State Health Mission”. There is provision of a “mobile medical unit” at district level for improved outreach services.

Since almost 75 per cent of health services are being currently provided by the private sector, it is contemplated that involving the private sector as part of the RCH initiatives will provide more effective health care delivery system. Thus setting up of “Public Private Partnership” (PPP) is to help to make the RCH II programme better, and ensure availability of preventive and curative reproductive and child health services to the community.

**Major initiatives under NRHM**

1. **Selection of ASHA**: ASHA must be the resident of the village – a woman (married / widow / divorced) preferably in the age group of 25 to 45 years with formal education up to eighth class, having communication skills and leadership qualities. Adequate representation from the disadvantaged population group will ensure to serve such groups better.

The general norm of selection is one ASHA for 1000 population. In tribal, hilly and desert areas the norm could be relaxed to one ASHA per habitation.

2. **Rogi Kalyan Samiti (Patient Welfare Committee/Hospital Management Society)**: It is a simple yet effective management structure. This committee is a registered society whose members act as trustees to manage the affairs of the hospital and is responsible for upkeep of the facilities and ensure provision of better facilities to the patients in the hospital. Financial assistance is provided to these Committees through unified fund to undertake activities for patient welfare. 32,005 Rogi Kalyan Samities (RKS) have been set up involving the community members in almost all District Hospitals (DHs), Sub-District Hospitals (SDHs), Community Health Centres (CHCs) and Primary Health Centres (PHCs) till March 2015.

3. **The untied grants to sub-centres (SCs)**: The SCs are far better equipped now with blood pressure measuring equipment, haemoglobin (Hb) measuring equipment, stethoscope, weighing machine etc. This has facilitated provision of quality antenatal care and other health care services.

4. **The Village Health Sanitation and Nutrition Committee (VHSNC)**: It is an important tool of community empowerment and participation at the grassroots level. The VHSNC reflects the aspirations of the local community, especially the poor households and children. During the year 2015, 5.01 lakh VHSNCs have been set up across the country.

5. **Janani Suraksha Yojana (JSY)**: aims to reduce maternal mortality among pregnant women by encouraging them to deliver in government health facilities. Under the scheme, cash assistance is provided to eligible pregnant women for giving birth in a government health facility. Since the inception of NRHM, 8.55 crore women have benefited under this scheme. For details please refer to page 491.

6. **Janani Shishu Suraksha Karyakram (JSSK)**: Launched on 1st June, 2011, JSSK entitles all pregnant women delivering in public health institutions to absolutely free and no expense delivery, including caesarean section. This scheme has paved the way for reducing maternal mortality among pregnant women by encouraging them to deliver in government health facilities. Since the inception of NRHM, 8.55 crore women have benefited under this scheme. For details please refer to page 492 for details.

7. **National Mobile Medical Units (NMMUs)**: Support has been provided in 402 out of 673 districts for 1360 MMUs under NRHM in the country. To increase visibility, awareness and accountability, all Mobile Medical Units have been repositioned as “National Mobile Medical Unit Service” with universal colour and design.

8. **National Ambulance Services**: NRHM has supported free ambulance services to provide patients transport in every nook and corner of the country connected with a toll free number. Currently, 32 states/UTs have the facility where people can dial 108 or 102 telephone number for calling an ambulance. Dial 108 is predominantly an emergency response system, primarily designed to attend to patients of critical care, trauma and accident victims etc. Dial 102 services essentially consist of basic patient transport aimed to cater the needs of pregnant women and children though other categories are also taking benefit and are not excluded. Janani Shishu Suraksha Karyakram (JSSK) entitlements e.g. free transport from home to facility, inter facility transfer in case of referral and drop back for mother and children are the key focus of 102 service. This service can be accessed through a toll free call to a Call Centre (7).

Presently, 8680 Dial-108, 603 Dial-104 and 8718 Dial-102 Emergency Response Service Vehicles are operational under NRHM, besides 5859 empaneled vehicles are for
transportation of patients, particularly pregnant women and sick infants from home to public health facilities and back (7).

9. Web enabled Mother and Child Tracking System (MCTS): The name-based tracking of pregnant women and children has been initiated under NRHM with an intention to track every pregnant woman, infant and child up to the age of three years by name, for ensuring delivery of services like timely antenatal care, institutional delivery and postnatal care for the mother, and immunization and other related services for the child. The MCTS is to be fully updated for regular and effective monitoring of service delivery. Including tracking and monitoring of severely anaemic women, low birth weight babies and sick neonates. In the long run, it could be used for tracking the health status of the girl child and school health services. A more recent initiative is to link MCTS with Aadhar in order to track subsidies to eligible women (49).

New initiatives (43)
The following are the major decisions of Mission Steering Group; taken since 2011:

1. Home delivery of contraceptives (condoms, oral contraceptive pills, emergency contraceptive pills) by ASHA;
2. Conducting District Level Household Survey (DLHS) – 4 in 26 States/UTs where the Annual Health Survey (AHS) is not being done;
3. Modifications in the scheme for promotion of menstrual hygiene covering 152 districts and nearly 1.5 crores of adolescent girls in 20 states;
4. Differential financial approach for comprehensive health care by which allocation of Unified Funds and Rogi Kalyan Samiti grants will be made based on the case load and services provided by the health facility;
5. Involving ASHA in Home Based Newborn Care;
6. Revision in the criterion of allocation of funds to the states under NRHM based on the performance of the states against the monitorable targets and implementation of specific reform agenda in the health sector;
7. Expansion of Village Health and Sanitation Committees to include nutrition in its mandate and renaming it as Village Health, Sanitation and Nutrition Committee (VHSNC);
8. Partial modification of the centrally sponsored scheme for development of Ayush hospitals and dispensaries for mainstreaming of Ayush under NRHM;
9. Rashtriya Bal Swasthya Karyakram (RBSK): This initiative was launched in February 2013 and provides for Child Health Screening and Early Intervention Services through early detection and management of 4 Ds i.e., Defects at birth, Diseases, Deficiencies, Development delays including disability. For details please refer to page 498;
10. Rashtriya Kishor Swasthya Karyakram (RKS): This is a new initiative, launched in January 2014 to reach out to 253 million adolescents in the country in their own spaces and introduces peer-led interventions at the community level, supported by augmentation of facility based services. This initiative broadens the focus of the adolescent health programme beyond reproductive and sexual health and brings in focus on life skills, nutrition, injuries and violence (including gender based violence), non-communicable diseases, mental health and substance misuse (11);
11. Mother and Child Health Wings (MCH Wings): 100/50/30 bedded Maternal and Child Health (MCH) Wings have been sanctioned in public health facilities with high bed occupancy to cater to the increased demand for services. More than 3.2,000 additional beds have been sanctioned across 550 health facilities across 18 states;
12. Free drugs and free diagnostic service;
13. National Iron+ Initiative is another new initiative launched in 2013, to prevent and control iron deficiency anaemia, a grave public health challenge in India. Besides pregnant women and lactating mothers, it aims to provide IFA supplementation for children, adolescents and women in reproductive age group. Weekly Iron and Folic Acid Supplementation (WIFS) for adolescents is an important strategy under this initiative. WIFS (for 10-19 years age) has already been rolled out in 32 states and UTs under the National Iron plus Initiative. WIFS covered around 3 crore beneficiaries in December 2013 (1);
14. Reproductive, Maternal, Newborn, Child and Adolescent Health Services (RMNCH+A): A continuum of care approach has now been adopted under NRHM with the articulation of strategic approach to Reproductive Maternal, Newborn, Child and Adolescent Health (RMNCH+A) in India. This approach brings focus on adolescents as a critical life stage and linkages between child survival, maternal health and family planning efforts. It aims to strengthen the referral linkages between community and facility based health services and between the various levels of health system itself. Please refer to page 499 for details;
15. Delivery Points (DPs): Health facilities that have a high demand for services and performance above a certain benchmark have been identified as "Delivery Points" with the objective of providing comprehensive reproductive, maternal, newborn, child and adolescent health services (RMNCH+A) at these facilities. Funds have been allocated to strengthen these DPs in terms of infrastructure, human resource, drugs, equipment etc. Around 17,000 health facilities have been identified as "Delivery Points" for focussed support under NRHM;
16. Universal Health Coverage (UHC): Moving towards Universal Health Coverage (UHC) is a key goal of the 12th Five Year Plan. The National Health Mission is the primary vehicle to move towards this goal;
17. Comprehensive primary healthcare: Nine areas for action to make primary healthcare comprehensive and universal are proposed. They are (6):

a. Strengthen institutional structures and organization of primary healthcare services;
b. Improve access to technologies, drugs and diagnostics for comprehensive primary healthcare;
c. Increase utilization of Information, Communication and Technology (ICT) - empowering patients and providers;
d. Promote continuity of care - making care patient centric;
e. Enhance quality of care;
f. Focus on social determinants of health;
g. Emphasize community participation and address equity concerns in health;
h. Develop a human resource policy to support primary healthcare;
i. Strengthen governance including financing, partnerships and accountability; and
j. States are also offered support through the PIPs of the NHM to strengthen existing sub-centres.
Interventions in all districts
- Child Survival interventions i.e. immunization, Vitamin A (to prevent blindness), oral rehydration therapy and prevention of deaths due to pneumonia.
- Safe Motherhood interventions e.g. antenatal check up, immunization for tetanus, safe delivery, anaemia control programme.
- Implementation of Target Free Approach.
- High quality training at all levels.
- IEC activities
- Specially designed RCH package for urban slums and tribal areas
- District sub-projects under Local Capacity Enhancement.
- RTI/STD Clinics at District Hospitals (where not available)
- Facility for safe abortions at PHCs by providing equipment, contractual doctors etc.
- Enhanced community participation through Panchayats. Women's Groups and NGOs.
- Adolescent health and reproductive hygiene.

Interventions in selected States/Distts.
- Screening and treatment of RTI/STD at sub-divisional level.
- Emergency obstetric care at selected FRUs by providing drugs.
- Essential obstetric care by providing drugs and PHN/Staff Nurse at PHCs.
- Additional ANM at sub-centres in the weak districts for ensuring MCH care.
- Improved delivery services and emergency care by providing equipment kits, IUD insertions and ANM kits at sub-centres.
- Facility of referral transport for pregnant women during emergency to the nearest referral centre through Panchayat in weak districts.

The major interventions under RCH – Phase I

Essential obstetric care (51)

Essential obstetric care intends to provide the basic maternity services to all pregnant women through (1) early registration of pregnancy (within 12–16 weeks), (2) provision of minimum three antenatal check ups by ANM or medical officer to monitor progress of the pregnancy and to detect any risk/complication so that appropriate care including referral could be taken in time, (3) provision of safe delivery at home or in an institution, and (4) provision of three postnatal check ups to monitor the postnatal recovery and to detect complications.

Emergency obstetric care

Complications associated with pregnancy are not always predictable. Hence, emergency obstetric care is an important intervention to prevent maternal morbidity and mortality. Under the CSSM programme 1748 Referral Units were identified and supported with equipment. Kit E to kit P. Under the RCH programme the FRUs were strengthened through supply of emergency obstetric kit, equipment kit and provision of skilled manpower on contract basis etc. Traditional Birth Attendant still plays an important role during deliveries in our society.

18. Kilkari: Kilkari is an Interactive Voice Response (IVR) based mobile service that delivers time-sensitive audio messages (voice call) about pregnancy and child health directly to the mobile phones of pregnant women, mothers of young children and their families. The service covers the critical time period— where the most maternal/infant deaths occur from the 4th month of pregnancy until the child is one year old. Families which subscribe to the service receive one pre-recorded system generated call per week. Each call will be 2 minutes in length and serve as reminders for what the family should be doing that week depending on woman's stage of pregnancy or the child's age. Kilkari services will be available to states in regional dialect too (6):

19. Launch of Nationwide anti-TB drug resistance survey:
Drug resistance survey for 13 anti-tuberculosis drugs was launched to estimate the burden of MDR-TB within the community. It is the biggest ever such survey in the world; and

20. Kala-azar elimination plan: Kala-azar elimination plan for Uttar Pradesh, Bihar, West Bengal and Jharkhand was launched. It includes active search, new drug regimen, coordinated indoor residual spray and use of non-invasive diagnostic kit.

Reproductive and child health programme

Reproductive and child health approach has been defined as "people have the ability to reproduce and regulate their fertility, women are able to go through pregnancy and child birth safely, the outcome of pregnancies is successful in terms of maternal and infant survival and well being, and couples are able to have sexual relations, free of fear of pregnancy and of contracting disease" (50).

The concept is in keeping with the evolution of an integrated approach to the programme aimed at improving the health status of young women and young children which has been going on in the country namely family welfare programme, universal immunization programme, oral rehydration therapy, child survival and safe motherhood programme and acute respiratory infection control etc. It is obviously sensible that integrated RCH programme would help in reducing the cost inputs to some extent because overlapping of expenditure would not be necessary and integrated implementation would optimise outcomes at field level.

The RCH phase-I programme incorporated the components relating child survival and safe motherhood and included two additional components, one relating to sexually transmitted disease (STD) and other relating to reproductive tract infection (RTI).

The RCH programme was based on a differential approach. Inputs in all the districts were not kept uniform. While the care components was same for all districts, the weaker districts got more support and sophisticated facilities were proposed for relatively advanced districts. On the basis of crude birth rate and female literacy rate, all the districts were divided into three categories. Category A having 58 districts, category B having 184 districts and category C having 265 districts. All the districts were covered in a phased manner over a period of three years. The programme was formally launched on 15th October 1997.

RCH phase-I interventions at district level were as follows:

Interventions in selected States/Distts.
- Screening and treatment of RTI/STD at sub-divisional level.
- Emergency obstetric care at selected FRUs by providing drugs.
- Essential obstetric care by providing drugs and PHN/Staff Nurse at PHCs.
- Additional ANM at sub-centres in the weak districts for ensuring MCH care.
- Improved delivery services and emergency care by providing equipment kits, IUD insertions and ANM kits at sub-centres.
- Facility of referral transport for pregnant women during emergency to the nearest referral centre through Panchayat in weak districts.
24-Hour delivery services at PHCs/CHCs

To promote institutional deliveries, provision has been made to give additional honorarium to the staff to encourage round the clock delivery facilities at health centres.

Medical Termination of Pregnancy

MTP is a reproductive health measure that enables a woman to opt out of an unwanted or unintended pregnancy in certain specified circumstances without endangering her life, through MTP Act 1971. The aim is to reduce maternal morbidity and mortality from unsafe abortions. The assistance from the Central Government is in the form of training of manpower, supply of MTP equipment and provision for engaging doctors trained in MTP to visit PHCs on fixed dates to perform MTP.

Control of reproductive tract infections (RTI) and sexually transmitted diseases (STD)

Under the RCH programme, the component of RTI/STD control is linked to HIV and AIDS control. It has been planned and implemented in close collaboration with National AIDS Control Organization (NACO). NACO provides assistance for setting up RTI/STD clinics up to the district level. The assistance from the Central Government is in the form of training of the manpower and drug kits including disposable equipment. Each district is assisted by two laboratory technicians on contract basis for testing blood, urine and RTI-STD tests.

Immunization

Essential newborn care

The primary goal of essential newborn care is to reduce perinatal and neonatal mortality. The main components are resuscitation of newborn with asphyxia, prevention of hypothermia, prevention of infection, exclusive breast feeding and referral of sick newborn. The strategies are to train medical and other health personnel in essential newborn care, provide basic facilities for care of low birth weight and sick new borns in FRU and district hospitals etc.

Diarrhoeal disease control

In the districts not implementing Integrated Management of Neonatal and Childhood Illness, the vertical programme for control of diarrhoeal disease will continue. India is the first country in the world to introduce the low osmolality Oral Rehydration Solution. Zinc is to be used as an adjunct to ORS for the management of diarrhoea. Addition of Zinc would result in reduction of the number and severity of episodes and the duration of diarrhoea. De-worming guidelines have been formulated. The incidence of diarrhoea is reduced by provision of safe drinking water.

Acute respiratory disease control

The standard case management of ARI and prevention of deaths due to pneumonia is now an integral part of RCH programme. Peripheral health workers are being trained to recognize and treat pneumonia. Cotrimoxazole is being supplied to the health workers through the drug kit.

Prevention and control of vitamin A deficiency in children

It is estimated that large number of children suffer from sub-clinical deficiency of vitamin A. Under the programme, doses of vitamin A are given to all children under 5 years of age. The first dose (1 lakh units) is given at nine months of age along with measles vaccination. The second dose (2 lakh units) is given after 9 months. Subsequent doses (2 lakh units each) are given at six months intervals up to 5 years of age (3). All cases of severe malnutrition to be given one additional dose of vitamin A.

Prevention and control of anaemia in children

Iron deficiency anaemia is widely prevalent in young children. To manage anaemia, the policy has been revised. Infants from the age of 6 months onwards up to the age of 5 years are to receive iron supplements in liquid formulation in doses of 20 mg elemental iron and 100 mcg folic acid per day for 100 days in a year. Children 6 to 10 years of age will receive iron in the dose of 30 mg elemental iron and 250 mcg folic acid for 100 days in a year. Children above this age group would receive iron supplement in the adult dose (3).

Training of dais

A scheme for training of dais was initiated during 2001–02. The scheme is being implemented in 156 districts in 18 states/UTs of the country. The districts have been selected on the basis of the safe delivery rates being less than 30 per cent. The scheme was extended to all the districts of EAG states. The aim was to train at least one Dai in every village, with the objective of making deliveries safe.

Empowered Action Group (EAG)

An Empowered Action Group has been constituted in the Ministry of Health and Family Welfare, with Union Minister for Health and Family Welfare as chairman on 20th March 2001. As 55 per cent of the increase in the population of India is anticipated in the states of Uttar Pradesh, Bihar, Madhya Pradesh, Rajasthan, Odisha, Chattisgarh, Jharkhand and Uttarakhand, these states are perceived to be most deficient in critical socio-demographic indices. Through EAG, these states will get focussed attention for different health and family welfare programmes.

District Surveys

There is no regular source of data to indicate the reproductive health status of women. The RCH programme conducts district based rapid household survey to assess the reproductive health status of women. The key indicators are:

- Percentage of pregnant women with full ANC;
- Percentage of institutional deliveries and home deliveries;
- Percentage of home deliveries by trained birth attendant;
- Current contraceptive prevalence rate;
- Percentage of children fully immunized;
- Percentage of unmet need for family planning; and
- Percentage of household reported visits by health worker in previous 3 months.

**RCH – PHASE II**

RCH–phase II began from 1st April, 2005. The focus of the programme is to reduce maternal and child morbidity and mortality with emphasis on rural health care.

The major strategies under the second phase of RCH are (52):

- **Essential obstetric care**
  a. Institutional delivery.
  b. Skilled attendance at delivery.

- **Emergency obstetric care**
  a. Operationalizing First Referral Units.
  b. Operationalizing PHCs and CHCs for round the clock delivery services.

- **Strengthening referral system**

The Government of India has given some broad guidelines and strategies for achieving the reduction in maternal mortality rate and infant mortality rate. The initiatives which have been planned are:

**Essential obstetric care**

a. Institutional delivery – To promote institutional delivery in RCH Phase II, it was envisaged that fifty percent of the PHCs and all the CHCs would be made operational as 24-hour delivery centres, in a phased manner, by the year 2010. These centres would be responsible for providing basic emergency obstetric care and essential newborn care and basic newborn resuscitation services round the clock. The experience of RCH phase-I indicates that giving incentive to health workers for providing round the clock services did not function well in most of the states. On the contrary there is the experience from government of Andhra Pradesh and Tamil Nadu, where round the clock delivery and newborn care services could be ensured by providing 3 to 4 staff nurses/ANM at the PHCs.

b. Skilled attendance at delivery – It is now recognized globally that the countries which have been successful in bringing down maternal mortality are the ones where the provision of skilled attendance at every birth and its linkage with appropriate referral services for complicated cases have been ensured. The WHO has also emphasized that skilled attendance at every birth is essential to reduce the maternal mortality in any country. Guidelines for normal delivery and management of obstetric complications at PHC/CHC for medical officers and for ANC and skilled attendance at birth for ANM/LHVs have been formulated and disseminated to the states.

c. The policy decisions: ANMs / LHVs / SNs have now been permitted to use drugs in specific emergency situations to reduce maternal mortality. They have also been permitted to carry out certain emergency interventions when the life of the mother is at stake.

**Emergency obstetric care**

Operationalization of FRUs and skilled attendance at birth are the two activities which go hand in hand. In view of this, simultaneous steps have been taken to ensure tackling obstetric emergencies. It has been decided that all the First Referral Units be made operational for providing emergency and essential obstetric care during the second phase of RCH. The minimum services to be provided by a fully functional FRU are (53):

1. 24 hours delivery services including normal and assisted deliveries;
2. Emergency obstetric care including surgical interventions like caesarean sections;
3. New-born care;
4. Emergency care of sick children;
5. Full range of family planning services including laparoscopic services;
6. Safe abortion services;
7. Treatment of STI/RTI;
8. Blood storage facility;
9. Essential laboratory services; and
10. Referral (transport) services.

There are three critical determinants of a facility being ‘declared’ as a FRU. They are: availability of surgical interventions, new-born care and blood storage facility on a 24 hours basis.

To be able to perform the full range of FRU function, a health facility must have the following facilities:

- a) A minimum bed strength of 20-30. However, in difficult areas, as the North–East states and the underserved areas of EAG states, this could initially be relaxed to 10-12 beds;
- b) A fully functional operation theatre;
- c) A fully functional labour room;
- d) An area earmarked and equipped for newborn care in the labour room, and in the ward;
- e) A functional laboratory;
- f) Blood storage facility;
- g) 24 hour water supply and electricity supply;
- h) Arrangements for waste disposal;
- i) Ambulance facility.

**Strengthening referral system**

During RCH phase-I, funds were given to the Panchayats for providing assistance to poor people in the case of obstetric emergencies. Feedback from the states indicate that there was no active involvement of Panchayats in running the scheme. Based on these experiences different states have proposed different modes of referral linkage in RCH Phase II. Some of them have indicated to involve local self help groups, NGOs and women groups, whereas few others have indicated to outsource it.

**New initiatives**

1. Training of MBBS doctors in life saving anaesthetic skills for emergency obstetric care: Provision of adequate and timely emergency obstetric care (EmOC) has been recognized as the most important intervention for saving lives of pregnant women who may develop complications during pregnancy or childbirth. The operationalisation of First Referral Unit at sub-district/CHC level for providing EmOC to pregnant women is a crucial strategy of RCH-II, which needs focussed attention. The training of MBBS doctors will be undertaken for only such numbers who are required for the functioning of FRUs and CHCs, and shall be limited to the requirement of tackling emergency obstetric situations only. It is not the replacement of the specialist anaesthetist. Government of India is also introducing training of MBBS doctors in obstetric management skills. Federation of Obstetric and Gynaecology Society of India has prepared a training plan for 16 weeks in all obstetric management skills, including caesarean section operation.
2. Setting up of blood storage centres at FRUs according to government of India guidelines.

**JANANI SURAKSHA YOJANA**

The National Maternity Benefit scheme has been modified into a new scheme called Janani Suraksha Yojana (JSY). It was launched on 12th April, 2005. The objectives of scheme are – reducing maternal mortality and neonatal mortality through encouraging delivery at health institutions, and focusing at institutional care among women in below poverty line families.

The salient features of Janani Suraksha Yojana are as follows (7):

a. It is a 100 per cent centrally sponsored scheme;
b. Under National Rural Health Mission, it integrates the benefit of cash assistance with institutional care during antenatal, delivery and immediate post-partum care; this benefit will be given to all women, both rural and urban, belonging to below poverty line household.

However, with a view to give special focus in 10 low performing states (states having low institutional delivery rate), namely Uttar Pradesh, Uttarakhand, Madhya Pradesh, Jharkhand, Bihar, Rajasthan, Chattisgarh, Odisha, Assam and Jammu & Kashmir, the benefit will be extended up to the third child if the mother, of her own accord, chooses to undergo sterilization in the health facility where she delivered, immediately after delivery. The other states are called high performing states. The Accredited Social Health Activist (ASHA) would work as a link health worker between the poor pregnant women and public sector health institution in the low performing states. ASHA would be responsible for making available institutional antenatal as well as postnatal care. She would also be responsible for escorting the pregnant women to the health centre. The scale of assistance under the scheme from 2012–13 would be as follows:

<table>
<thead>
<tr>
<th>Category</th>
<th>Rural Area</th>
<th>Urban Area</th>
</tr>
</thead>
<tbody>
<tr>

<td>600</td>
</tr>
</tbody>
</table>

LPS: Low performing states, HPS: High performing states
* ASHA incentive of Rs. 600/- in rural areas includes Rs. 300/- for ANC component and Rs. 300/- for accompanying pregnant woman for institutional delivery
** ASHA incentive of Rs. 400/- in urban area includes Rs. 200/- for ANC component and Rs. 200/- for accompanying pregnant woman for institutional delivery

Source: (7)

The eligibility of cash assistance is as follows (7):

1. In low performing states (LPS): All women, including those from SC and ST families, delivering in government health centres like sub-centre, primary health centre, community health centre, first referral unit, general wards of district and state hospitals or accredited private institutions.
2. In high performing states (HPS): Below poverty line women, and the SC and ST pregnant women delivering in Govt. health centres or accredited private institutes.

The limitation of cash assistance for institutional delivery is as follows:

1. In low performing states: All births, delivered in health centre, government or accredited private health institutions will get the benefit.
2. In high performing states: the benefit is only up to 2 live births.

ASHA package is available in all low performing states, North-East states and in tribal districts of all states and UTs. In rural areas it includes the following components:

- (a) Cash assistance for referral transport for pregnant women to get to the nearest health centre for delivery (should not be less than Rs. 250/-);
- (b) Cash incentive: This should not be less than Rs. 200/- per delivery. ASHA should get her money after her post-natal visit to the beneficiary, and when the child has been immunized for BCG; and
- (c) Balance amount to be paid to ASHA in lieu of her services rendered by her. The payment should be made at the hospital/health institution itself.

The Yojana subsidizes the cost of caesarean section and for management of obstetric complications, up to Rs. 1500 per delivery to the government institutions, where government specialists are not in position.

In low performing and high performing states, all below poverty line pregnant women preferring to deliver at home, are entitled to cash assistance of Rs. 500 per delivery, regardless of age and number of children (7).

**Direct benefit transfer under JSY**: Payments under the JSY are being made through direct benefit transfer mode. Under this initiative, eligible pregnant women are entitled to get JSY benefit directly into their Aadhar linked bank account/electronic fund transfer (7).

The year 2006-07 was declared as the year for institutional deliveries. During the year scope of the scheme was extended to the urban areas of high performing states and restriction of age and birth order were removed in the low performing states. The benefits of the scheme was also extended to all women belonging to SC/ST families for institutional deliveries.

During the year 2015–16, about 104.16 lakh pregnant women were benefitted from the scheme (7).

**Vandemataram scheme**

This is a voluntary scheme wherein any obstetric and gynaec specialist, maternity home, nursing home, lady doctor, MBBS doctor can volunteer themselves for providing safe motherhood services. The enrolled doctors will display 'Vandemataram logo' at their clinic. Iron and Folic Acid tablets, oral pills, TT injections etc. will be provided by the respective District Medical Officers to the 'Vandemataram doctors/clinics' for free distribution to beneficiaries. The cases needing special care and treatment can be referred to the government hospitals, who have been advised to take due care of the patients coming with Vandemataram cards.

**Safe abortion services**

In India, abortion is a major cause of maternal mortality and morbidity and accounts for nearly 8.9 per cent maternal deaths. Majority of abortions take place outside authorized health services and/or by unauthorized and unskilled persons. Whether spontaneous or induced, abortion is a matter of concern as it may lead to complications. Under RCH phase II following facilities are provided:
a. **Medical method of abortion**: Termination of early pregnancy with two drugs – Mifepristone (RU 486) followed by Misoprostol. They are considered safe under supervision, with appropriate counselling. Currently its use in India is recommended up to 7 weeks (49 days) of amenorrhoea in a facility with provision for safe abortion services and blood transfusion. Termination of pregnancy with RU 486 and Misoprostol is offered to women under the preview of the MTP Act, 1971.

b. **Manual Vacuum Aspiration (MVA)**: The Department of family welfare has introduced Manual Vacuum Aspiration (MVA) technique in the family welfare programme. Manual Vacuum Aspiration is a safe and simple technique for termination of early pregnancy, making it feasible to be used in primary health centres or comparable facilities, thereby increasing access to safe abortion services. The project of introducing the MVA technique has been piloted in coordination with FOGSI, WHO and respective state governments before being accepted for implementation by the ministry of health and family welfare.

**Village Health and Nutrition Day**
Organizing Village Health and Nutrition Day once a month at anganwadi centre to provide antenatal/post-partum care for pregnant women, promote institutional delivery, health education, immunization, family planning and nutrition services etc.

**Maternal death review**
Maternal death review as a strategy has been spelt out clearly in the RCH-II. Maternal death audit, both facility and community based, is an important strategy to improve the quality of obstetric care and reduce maternal mortality and morbidity. Guidelines and tools for initiating maternal death review have been formulated (3).

**Pregnancy tracking**
The link between pregnancy-related care and maternal mortality is well established. RCH-II stresses the need for universal screening of pregnant women and providing essential and emergency obstetric care. Focussed antenatal care, birth preparedness and complication readiness, skilled attendance at birth, care within the first seven days etc. are the factors that can reduce the maternal mortality (3).

**JANANI-SHISHU SURAKSHA KARYAKRAM (JSSK)**
Government of India launched the Janani-Shishu Suraksha Karyakram (JSSK) on 1st June 2011, a new national initiative, to make available better health facilities for women and child. The new initiatives provide the following facilities to pregnant women (54):
- All pregnant women delivering in public health institutions to have absolutely free and no expense delivery, including caesarean section. The entitlements include free drugs and consumables, free diet up to 3 days during normal delivery and up to 7 days for C-section, free diagnostics, and free blood wherever required. This initiative would also provide for free transport from home to institution, between facilities in case of a referral and drop back home. Similar entitlements have been put in place for all sick newborns accessing public health institutions for treatment till 30 days after birth. The scheme has now been extended to cover the complications during ANC, PNC and also sick infants.
- The scheme is estimated to benefit more than 12 million pregnant women who access government health facilities for their delivery. Moreover, it will motivate those who still choose to deliver at their homes to opt for institutional deliveries.

**Child health components**
The strategy for child health care, aims to reduce under-five child mortality through interventions at every level of service delivery and through improved child care practices and child nutrition.

**Nutritional rehabilitation centres (NRCs)**
Severe acute malnutrition is an important contributing factor for most deaths among children suffering from common childhood illness such as diarrhoea and pneumonia. Deaths among these malnourished children are preventable, provided timely and appropriate actions are taken. NRCs are facility based units providing medical and nutritional care to Severe Acute Malnutrition (SAM) children under 5 years of age who have medical complications. In addition special focus is on improving the skill of mothers on child care and feeding practices so that the child continues to get adequate care at home. The services provided at the NRCs include (1):

a. 24 hours care and monitoring of the child;
b. Treatment of medical complication;
c. Therapeutic feeding;
d. Sensory stimulation and emotional care;
e. Counselling on appropriate feed, care and hygiene;
f. Demonstration and practice-by-doing on the preparation of energy dense food using locally available, culturally acceptable and affordable food items;
g. Social assessment of the family to identify and address contributory factors; and
h. Follow up of the children discharged from the facility.

**Management of medical complications in a child with SAM at health facility** (55)
A majority of the deaths in hospitals occur within 24 hours of admission, many of these deaths can be prevented if the critically ill children are identified as soon as they are admitted and their treatment is started immediately.

**Triage**
Triage is the process of rapidly screening sick children. Triage must be done for all paediatric patients coming to the health facility. The first step is to check every child for emergency signs and provide emergency treatment as necessary, keeping in mind the ABCD steps: Airway, Breathing, Circulation, Coma, Convulsion and Dehydration.

**Assessment at admission** (55)
The child should be assessed by taking detailed history and should be examined for the signs of under-nutrition.
Principles of hospital-based management (55)

The principles of management of SAM are based on 3 phases: stabilization phase, transition phase and rehabilitative phase.

Stabilization Phase: Children with SAM without an adequate appetite and/or a major medical complication are stabilized in an in-patient facility. This phase usually lasts for 1-2 days. The feeding formula used during this phase is Starter diet which promotes recovery of normal metabolic function and nutrition — electrolytic balance. All children must be carefully monitored for signs of overfeeding or over hydration in this phase.

Transition Phase: This phase is the subsequent part of the stabilization phase and usually lasts for 2-3 days. The transition phase is intended to ensure that the child is clinically stable and can tolerate an increased energy and protein intake. The child moves to the Transition Phase from Stabilization Phase when there is:
- At least the beginning of loss of oedema.

AND

- Return of appetite.

AND

- No nasogastric tube, infusions, no severe medical problems.

AND

- Is alert and active?

The ONLY difference in management of the child in transition phase is the change in type of diet. There is gradual transition from starter diet to catch up diet. The quantity of catch up diet given is equal to the quantity of starter diet given in stabilization phase.

Rehabilitation Phase: Once children with SAM have recovered their appetite and received treatment for medical complications they enter Rehabilitation Phase. The aim is to promote rapid weight gain, stimulate emotional and physical development and prepare the child for normal feeding at home. The child progresses from transition phase to rehabilitation phase when:

- S/he has reasonable appetite; finishes > 90% of the food that is given, without a significant pause.
- Major reduction or loss of oedema
- No other medical problem.

Micronutrient supplementation (55)

Vitamin A: Give Vitamin A in a single dose to all SAM children unless there is evidence that child has received vitamin A dose in last 1 month.

Recommended oral dose of Vitamin A according to child’s age:

<table>
<thead>
<tr>
<th>Age</th>
<th>Vit. A dose</th>
</tr>
</thead>
<tbody>
<tr>
<td>&lt;6 months</td>
<td>50,000 IU</td>
</tr>
<tr>
<td>6-12 months</td>
<td>100,000 IU</td>
</tr>
<tr>
<td>&gt;12 months</td>
<td>200,000 IU</td>
</tr>
</tbody>
</table>

- Give same dose on Day 1, 2 and 14 if there is clinical evidence of vitamin A deficiency.
- Children more than twelve months but having weight less than 8 kg should be given 100,000 IU orally irrespective of age.
- Oral treatment with vitamin A is preferred. For oral administration, an oil-based formulation is preferred.
- IM treatment should be used in children with severe anorexia, oedematous malnutrition, or septic shock. Only water based formulations and half of oral dose should be used.

Other micronutrients should be given daily for at least 2 weeks:
- Multivitamin supplement (should contain vitamin A, C, D, E and B12 and not just vitamin B complex): Twice recommended daily allowance.
- Folic acid: 5 mg on day 1, then 1 mg/day.
- Elemental Zinc: 2 mg/kg/day.
- Copper: 0.3 mg/kg/day (if separate preparation not available use commercial preparation containing copper).
- Iron: Start daily iron supplementation after two days of the child being on catch up diet. Give elemental iron in the dose of 3 mg/kg/day in two divided doses, preferably between meals. (DO NOT give iron in stabilization phase).

Follow up of children discharged from NRC

Close collaboration and information sharing between NRC and community based care (at PHC, sub-centre and AWC) are essential. The list of SAM children discharged from NRC should be shared with area specific ANM and ICDS supervisors. These children should be enrolled in the anganwadi centre and given supplementary food as per the guidelines. The AWWs should prioritize these children for home visits, every week in the first 4 weeks and then once in 2 weeks till the child is discharged from the programme. During the home visits, AWW should observe feeding and provide appropriate counselling and support to the mother. These children should be weighed every week at AWC. The ASHA and AWW should ensure that these children should return for the scheduled follow ups at the NRC (55). Incentive of Rs 50 can be provided to ASHA for accompanying the child to the NRC and motivating the mother to stay at NRC for atleast 7 days till the child is stabilized and has started to eat. Additional incentive of Rs 50 may be given for each follow up visit by the child, up to a maximum of three visits (55).

Presently 1148 NRCs are functional across 17 states/UTs (7).

Integrated Management of Neonatal and Childhood Illness (IMNCI)

IMNCI strategy is one of the main interventions under the RCH II/ NRHM. The strategy encompasses a range of interventions to prevent and manage the commonest major childhood diseases.

Pre-service IMNCI

Pre-service IMNCI has been accepted as an important strategy to scale up IMNCI by Govt. of India and is being included in the curriculum of medical colleges of the country. This will help in providing the much needed trained IMNCI manpower in the public and private sector.

Facility based IMNCI (F-IMNCI)

F-IMNCI is the integration of the facility based care package with the IMNCI package, to empower the health personnel with the skill to manage new born and childhood illness at the community level as well as the health facility. It focusses on providing appropriate inpatient management of the major causes of neonatal and childhood mortality such as asphyxia, sepsis, low birth weight, pneumonia, diarhoea, malaria, meningitis and severe malnutrition in children. The master trainers at state and district level are paediatricians from tertiary hospitals and medical colleges (3).

Facility based newborn care (56)

As more sick children are screened at the peripheries through IMNCI and referred to the health facilities, care of the sick newborn and child at CHCs, FRUs, district hospitals and medical college hospitals assumes priority. Equipping the facilities to provide the requisite level of care and simultaneously enhancing the capacity of the medical officers at these facilities to handle such cases thus becomes important. The setting up of SNCUs at district hospitals, stabilization units at CHCs, and newborn care corners at all facilities offering delivery facilities, is thus a key activity (3).

In the overall planning of facility based care it is important to understand the level of care that is provided at the various facility levels. The newborn care facilities at different levels are as follows:

<table>
<thead>
<tr>
<th>Health Level</th>
<th>All newborns at birth</th>
<th>Sick newborns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Primary health centre</td>
<td>Newborn care corner in labor rooms</td>
<td>Prompt referral</td>

</tr>
<tr>
<td>Identified as MCH Level II</td>
<td></td>
<td>Newborn stabilization unit</td>
</tr>
<tr>
<td>District hospital</td>
<td>Newborn care corner</td>
<td>Special newborn care unit</td>
</tr>
<tr>
<td>Identified as MCH Level III</td>
<td>operation theatre</td>
<td></td>
</tr>
</tbody>
</table>

Newborn Care Corner (NBCC)

NBCC is a space within the delivery room in any health facility where immediate care is provided to all newborns at birth. This area is MANDATORY for all health facilities where deliveries are conducted. As of Sept. 2017, about 18,323 NBCCs are operational in the country (7).

Newborn Stabilization Unit (NBSU)

NBSU is a facility within or in close proximity of the maternity ward where sick and low birth weight newborns can be cared for during short periods. All FRUs/CHCs need to have a neonatal stabilization unit, in addition to the newborn care corner. It requires space for 4 bedded unit and two beds in post-natal ward for rooming-in. As of Sept. 2017, 2,329 NBSUs are functional in the country.

Special Newborn Care Unit (SNCU)

SNCU is a neonatal unit in the vicinity of the labor room which is to provide special care (all care except assisted ventilation and major surgery) for sick newborns. Any facility with more than 3,000 deliveries per year should have an SNCU (most district hospitals and some sub-district hospitals would fulfill this criteria).

The minimum recommended number of beds for an SNCU at a district hospital is 12. However, if the district hospital conducts more than 3,000 deliveries per year, 4 beds should be added for each 1,000 additional deliveries. A 12 bedded unit will require 4 additional adult beds for the step down. As of Sept. 2017, 712 SNCUs are functional in the country.

Triage of sick newborns (56)

Triage is sorting of neonates to rapidly screen sick neonates for prioritizing management. Fig. 13 summarizes the process.

A. CRITERIA FOR ADMISSION TO NBSU (56):

- Newborn presenting with any of the following signs to a facility with neonatal stabilization unit requires admission for initial stabilization and transfer to SNCU:
  - Apnea or gasping
  - Respiratory distress (Rate>70/min with severe retractions/grunt)
Newborns classified as "Emergency" require urgent intervention and emergency measures. All such newborns will be admitted to SNCU after initial stabilization.

Newborns classified as "Priority" are sick and need rapid assessment and admission to SNCU.

Newborns classified as non-urgent do not require urgent attention, but require further assessment and counseling.

FIG. 13

- Hypothermia <35.4°C
- Hyperthermia (>37.5°C)
- Central cyanosis
- Shock (cold periphery with capillary filling time (CFT) more than 3 seconds and weak and fast pulse).
- Significant bleeding that requires blood or component transfusion.

Newborns, who after assessment and stabilization, can be managed at stabilization unit*.

- Newborns with respiratory distress, having respiratory rate 60-70/min without grunting or retractions (for observation and oxygen therapy).
- Newborns with gestation less than 34 weeks or weight <1800 g (for observation and assisted feeding).
- Newborns with hypothermia and hyperthermia who are haemodynamically stable after initial stabilization.
- Newborns with jaundice requiring phototherapy.
- Neonates with sepsis who are haemodynamically stable, for observation and antibiotic therapy

* Others would require referral to an SNCU after stabilization, if an SNCU and appropriate referral is available in the district.

B. CRITERIA FOR ADMISSION TO SNCU (56):

Criteria for admission to SNCU and criteria for transfer to step-down unit and discharge are as follows:

I. Any newborn with following criteria should be immediately admitted to the SNCU:
- Birth weight <1800 g or gestation <34 weeks.
- Large baby (>4.0 kg).
- Perinatal asphyxia.
- Apnea or gasping
- Refusal to feed.
- Respiratory distress (rate >60/min or grunt/retractions).
- Severe jaundice (appears <24 hrs/stains palms and soles/lasts >2 weeks).
- Hypothermia <35.4°C, or hyperthermia (>37.5°C).
- Central cyanosis.
- Shock (cold periphery with CFT >3 seconds, and weak and fast pulse).
- Coma, convulsions or encephalopathy.
- Abdominal distension.
II. Criteria for transfer from SNCU to the Step-Down:
- Newborn whose respiratory distress is improving and does not require oxygen supplementation to maintain saturation.
- Newborn on antibiotics for completion of duration of therapy.
- Low birth weight newborn (less than 1800 g), who are otherwise stable (for adequate weight gain).
- Newborn with jaundice requiring phototherapy but otherwise stable.
- Newborn admitted for any condition, but are now thermodynamically and hemodynamically stable.

III. Criteria for discharge from SNCU:
- Newborn is able to maintain temperature without radiant warmer.
- Newborn is haemodynamically stable (normal CFT, strong peripheral pulse).
- Newborn accepting breast-feeds well
- Newborn has documented weight gain for 3 consecutive days: and the weight is more than 1.5 kg
- Primary illness has resolved.

In addition to the above, mother should be confident of taking care of the newborn at home.

HOME BASED NEWBORN CARE (HBNC) (57):
Home based newborn care is aimed at improving newborn survival. The strategy of universal access to home based newborn care must complement the strategy of institutional delivery to achieve significant reduction in postpartum and neonatal mortality and morbidity. The providers of service include anganwadi workers, ANM, ASHA and the medical officer. However, ASHA is the main person involved in home based newborn care.

The major objective of HBNC is to decrease neonatal mortality and morbidity through:
1. The provision of essential newborn care to all newborns and the prevention of complications.
2. Early detection and special care of preterm and low birth weight newborns.
3. Early identification of illness in the newborn and provision of appropriate care and referral.
4. Support the family for adoption of healthy practices and build confidence and skills of the mother to safeguard her health and that of the newborn.

The responsibilities of ASHA for home based newborn care are as follows (57):
1. Mobilize all pregnant mothers and ensure that they receive the full package of antenatal care.
2. Undertake birth planning and birth preparedness with the mother and family to ensure access to safe delivery.
3. Provide newborn care through a series of home visits which include the skills for:
   a. Weighing the newborn;
b. Measuring newborn temperature;
c. Ensuring warmth;
d. Supporting exclusive breast-feeding by teaching the mother proper positioning and attachment for initiating and maintaining breast-feeding;
e. Diagnosing and counselling in case of problems with breast-feeding;
f. Promoting hand-washing;
g. Providing skin, cord and eye care;
h. Health promotion and counselling mothers and families on key messages on newborn care which includes discouraging unhealthy practices such as early bathing, and bottle feeding; and
i. Ensuring prompt identification of sepsis or other illnesses.

4. Assessing if the baby is high-risk (preterm or low birth weight), through the use of protocols and managing such LBW or preterm babies through:
   a. Increasing the number of home visits;
b. Monitoring weight gain; and
c. Supporting and counselling the mother and family to keep the baby warm and enabling frequent and exclusive breast-feeding.

5. Detect signs and symptoms of sepsis, provide first level care and refer the baby to an appropriate centre. If the family is unable to go, ASHA should ensure that the ANM visits sick newborn on a priority basis.

6. Recognize postpartum complications in the mother and refer appropriately.

7. Counsel the couple for family planning.

8. Provide immediate newborn care, in case of those deliveries that do not occur in institutions (home deliveries and deliveries occurring on the way to the institution).

ASHA will make visits to all newborns according to specified schedule upto 42 days of life. The schedule of visit is as follows:

b. Seven visits in the case of home delivery (Day 1, 3, 7, 14, 21, 28 and 42).
c. In cases of Caesarean section delivery, where the mother returns home after 5–6 days, ASHAs are entitled to full incentive of Rs. 250 if she completes all five visits starting from Day 7 to Day 42.
d. In cases when a newborn is discharged from SNCU, ASHAs are eligible to full incentive amount of Rs. 250 for completing the remaining visits. In addition, ASHAs are also eligible for an incentive of Rs. 50 for monthly follow-up of low birth weight babies and newborns discharged from SNCU (as approved by MSG of the National Health Mission on December 6th, 2013). The low birth weight are followed up for two years and SNCU discharged babies for one year.
e. In cases where the woman delivers at her maternal house and returns to her husband’s house, two ASHAs undertake the HBNC visits, i.e., one at maternal house immediately after delivery, and another one at
husband's house when the new-born returns home or vice versa. In such cases the HBNC incentive of Rs. 250 can be divided into two parts in a way that each ASHA who completes 3 visits or more is entitled to Rs. 125. In these instances, if an ASHA undertakes less than 3 visits, she would not be entitled to HBNC incentive.

f. In cases of twin or triplets the incentive amount for ASHA would be twice time of the regular HBNC incentive of Rs. 250/- (i.e., Rs. 500/-) or three times of Rs. 250/- (i.e., Rs. 750/-) respectively.

The incentive money is paid to ASHA on 45th day subject to the following:

a. Record of birth weight in the mother and child protection card;
b. Immunization of newborn with BCG, first dose of OPV, hep B and DPT/pentavalent vaccine and entry into the mother and child protection card;
c. Registration of birth; and
d. Both mother and newborn are safe until 42nd day of delivery.

Navjat Shishu Suraksha Karyakram (NSSK)

NSSK is a programme aimed to train health personnel in basic newborn care and resuscitation. It has been launched to address care at birth issue i.e. prevention of hypothermia, prevention of infection, early initiation of breast-feeding and basic newborn resuscitation. The objective of the new initiative is to have a trained health person in basic newborn care and resuscitation unit at every delivery point.

Integrated management of neonatal and childhood illness (IMNCI)

Integrated management of childhood illness (IMCI)

The extent of childhood morbidity and mortality caused by diarrhoea, ARI, malaria, measles and malnutrition is substantial. Most sick children present with signs and symptoms of more than one of these conditions. This overlap means that a single diagnosis may not be possible or appropriate, and treatment may be complicated by the need to combine for several conditions. An integrated approach to manage sick children is, therefore, necessary. IMCI is a strategy for an integrated approach to the management of childhood illness as it is important for child health programmes to look beyond the treatment of a single disease. This is cost effective and emphasizes prevention of disease and promotion of child health and development besides provision of standard care management of childhood illness.

In the Indian context this strategy is quite pertinent considering the evidence from NFHS–III report highlighting that ARI (17 per cent), diarrhoea (13 per cent), fever (27 per cent) and under-nutrition (43 per cent) were the commonest morbidities observed in the children aged under 3 years. Coverage of measles vaccination in children between 12–23 months was also low. An integrated approach to address these major childhood illnesses seems to be an effective strategy to promote child health in this country. The line of action is as shown in Fig. 14.

The Indian version of IMCI has been renamed as Integrated Management of Neonatal and Childhood Illness (IMNCI). It is the central pillar of child health interventions under the RCH II strategy. The major highlights of the Indian adaptation are:

a. Inclusion of 0–7 days age in the programme;
b. Incorporating national guidelines on malaria, anaemia, vitamin-A supplementation and immunization schedule;
c. Training of the health personnel begins with sick young infants up to 2 months;
d. Proportion of training time devoted to sick young infant and sick child is almost equal; and
e. Is skill based?

For more details please refer to page 631, chapter 10.

IMNCI strategy is one of the main interventions under RCH-II/NRHM. It focusses on preventive, promotive and curative aspects of the programme. The objective is to
implement IMNCI package at the level of household, and through ANMs at sub-centre level; through medical officers, nurses and LHV at PHCs level.

**Rashtriya Bal Swasthya Karyakram (RBSK)** (59)

RBSK is a new initiative launched in February 2013. It includes provision for Child Health Screening and Early Intervention Services through early detection and management of 4 Ds, prevalent in children. These are defects at birth, diseases in children, deficiency conditions and development delays including disabilities. An estimated 27 crore children in the age group of 0–18 years are expected to be covered across the country in a phased manner.

Child Health Screening and Early Intervention Services under NRHM envisage to cover 30 identified health conditions for early detection, free treatment and management. Based on the high prevalence of diseases like hypothyroidism, sickle cell anaemia and beta thalassaemia in certain geographical pockets of some states/UTs, and availability of testing and specialized support facilities, these states and UTs may incorporate them as part of this initiative. The health conditions are as shown in Table 13.

**Programme Implementation**

1. For newborn:
   - Facility based newborn screening at public health facilities, by existing health manpower.
   - Community based newborn screening at home through ASHAs for newborn till 6 weeks of age during home visits.

2. For children 6 weeks to 6 years:
   - Anganwadi centre based screening by dedicated Mobile Health Teams.

3. For children 6 years to 18 years:
   - Government and Government aided school based screening by dedicated Mobile Health Teams.

**Community based newborn screening (age 0-6 weeks) for birth defects**

Accredited Social Health Activists (ASHAs) during home visits for newborn care will use the opportunity to screen the babies born at home and the institutions till 6 weeks of age. ASHAs will be trained with simple tools for detecting gross birth defects. Further ASHAs will mobilise caregivers of children to attend the local Anganwadi Centres for screening by the dedicated Mobile Health Team. For performing the above additional tasks, she would be equipped with a tool kit consisting of a pictorial reference book having self-explanatory pictures for identification of birth defects. Suitable performance based incentive may also be provided to ASHAs.

**Screening of children aged 6 weeks till 6 years attending Anganwadi Centres**

Children in the age group 6 weeks to 6 years of age will be examined in the Anganwadi Centres by dedicated Mobile Health Teams.

**Screening of children enrolled in Government and Government aided schools**

For children in the age group 6 to 18 years, who will be screened in Government and Government aided schools, the block will be the hub of activity for the programme. At least two dedicated Mobile Health Teams in each block will be engaged to conduct screening of children. Villages within the jurisdiction of the block would be distributed amongst the mobile health teams. The number of teams may vary depending on the number of Anganwadi Centres, difficult to reach areas and children enrolled in the schools. The screening of children in the Anganwadi Centres would be conducted at least twice a year and at least once a year for school children to begin with.
In RCH Phase-II the other interventions of RCH Phase-I, e.g., additional ANMs, public health nurses, private anaesthetists, safe motherhood consultants, 24 hours delivery services at PHCs and CHCs, referral transports, integrated financial envelop, RCH camps, training of Dais, border district cluster strategy, and intervention for newborn care and child health (immunization, control of ARI and diarrhoea, vitamin A and iron supplementation etc.) will continue.

The quality indicators used to monitor and evaluate RCH programme through monthly reports are (60):

1. Number of antenatal cases registered - total and at least 12 weeks.
2. Number of pregnant women who had 3 antenatal check-ups;
3. Number of high-risk pregnant women referred.
4. Number of pregnant women who had two doses of tetanus toxoid injection;
5. Number of pregnant women under prophylaxis and treatment for anemia;
6. Number of deliveries by trained and untrained birth attendant;
7. Number of cases with complications referred to PHC/FRU;
8. Number of new born with birth weight recorded;
9. Number of women given 3 post natal check-ups;
10. Number of RTI/STI cases detected, treated and referred;
11. Number of children fully immunized;
12. Number of adverse reactions reported after immunization;
13. Number of cases of ARI and diarrhoea under 5 years treated, referred PHC/FRU and deaths; and
14. Number of cases motivated and followed up for contraception.

In June 2012, the Government of India, Ethiopia, USA and the UNICEF convened the "Global Child Survival Call to Action: A Promise to Keep" summit in Washington, DC to energize the global fight to end preventable child deaths through targeted interventions in effective, life-saving interventions for children. More than 80 countries gathered at the Call to Action to pledge to reduce child mortality to ≤ 20 child deaths per 1000 live births in every country by 2035 (57). Eight months after the event, in February 2013, the Government of India held its own historic Summit on the Call to Action for Child Survival, where it launched "A Strategic Approach to Reproductive, Maternal, Newborn, Child, and Adolescent Health (RMNCH+A) in India." Since that time, RMNCH+A has become the heart of the Government of India's flagship public health programme, the National Health Mission (61).

With support from USAID and its Maternal Child Health Integrated Programme (MCHIP), as well as from UNICEF, UNFPA, NIPJ and other development partners, the Government of India has taken important steps to introduce and support RMNCH+A implementation. This approach is likely to succeed given that India already has a community-based programme with presence of 9.15 lakh ASHA workers, as well as the three tiered health system in place. These provide a strong platform for delivery of services. This integrated strategy can potentially promote greater efficiency while reducing duplication of resources and efforts in the ongoing programme.

The RMNCH+A strategy is based on provision of comprehensive care through the five pillars, or thematic areas, of reproductive, maternal, neonatal, child, and adolescent health, and is guided by central tenets of equity, universal care, entitlement, and accountability. The "plus" within the strategy focuses on:

- Including adolescence for the first time as a distinct life stage;
- Linking maternal and child health to reproductive health, family planning, adolescent health, HIV, gender, preconception and prenatal diagnostic techniques;
- Linking home and community-based services to facility-based care; and
- Ensuring linkages, referrals, and counter-referrals between and among health facilities at primary (primary health centre), secondary (community health centre), and tertiary levels (district hospital).

In developing the RMNCH+A strategy, the aim is to reach the maximum number of people in the remotest corners of the country through a continuum of services, constant innovation, and routine monitoring of interventions. In rolling out the new strategy, the emphasis is on high impact interventions in each of the five thematic areas of reproductive, maternal, newborn, child, and adolescent health, and then to focus its efforts, and those of its development partners, on improving the coverage and quality of those interventions in 184 high-priority districts (HPDs) across India. Guidelines and tools were developed and policies were adjusted.

1. High-Priority Districts: The RMNCH+A strategy addresses India's inter-state and inter-district variations. The districts with relatively weak performance against RMNCH+A indicators were identified. Uniform and clearly defined criteria were used to identify 184 high-priority districts across all 29 states. The RMNCH+A approach is a conscious articulation of the GOI's commitment to tailoring programmes to meet the needs of previously underserved groups, including adolescents, urban poor, and tribal populations.

2. Management tools and job aids: The RMNCH+A 5x5 matrix identifies five high-impact interventions across each of the five thematic areas, five cross-cutting and health systems strengthening interventions, and the minimum essential commodities across each of the thematic areas. The 5x5 matrix as shown in Fig. 15, is an important tool for explaining the strategy in simple terms, organizing technical support, and monitoring progress with the states and high-priority districts.

Goals and Targets (49)

Taking into account the progress made so far in maternal and child health, it is pertinent to establish the goals and targets for the implementation phase 2012-2017, after considering the main reasons for mortality and interventions proven to have an impact on them. The 12th Five Year Plan has defined the national health outcomes and the three goals that are relevant to RMNCH+A strategic approach as follows:

- Reduction of Infant Mortality Rate (IMR) to 25 per 1,000 live births by 2017.
**Reproductive Health**
- Focus on spacing methods, particularly PPUCD at high case load facilities.
- Focus on interval IUCD at facilities including subcentres on fixed days.
- Home delivery of Contraceptives (HDC) and ensuring spacing at birth (LB) through ASHAs.
- Ensuring access to PACT kits (PTK 'Nuchay Kits) and strengthening comprehensive abortion care services.
- Maintaining quality sterilization services.

**Maternal Health**
- Use MCTS to ensure early registration of pregnancy and full ANC.
- Detect high risk pregnancies and one-list including severe anaemia, malnutrition, and ensure appropriate management.
- Equip delivery points with highly trained HR and ensure equitable access to EmOC services through TFRs and MCH wings as per need.
- Review maternal, infant, and child deaths for corrective actions.
- Identify villages with high numbers of births and contractions and distribute Misoprostol to selected women in the 8th month of pregnancy for consumption during 3rd stage of labour, incentivize ANMs for home deliveries.

**Newborn Health**
- Early initiation and exclusive breast-feeding.
- Home-based newborn care through ASHAs.
- Essential Newborn Care and resuscitation services at all delivery points.
- Special Newborn Care Units with trained human resource and other infrastructure.
- Communal level use of Gentamycin by ANM.

**Child Health**
- Complementary feeding, IFA supplementation and focus on nutrition.
- Home-based management at community level using ORS and zinc.
- Management of pneumonia.
- Full immunization coverage.
- Rashtriya Bal Swastha Kriyakram (RBSSK) - screening of children for 4Ds (birth defects, development delays, disabilities, and diseases) and full management.

**Adolescent Health**
- Address teenage pregnancy and increase contraceptive prevalence in adolescents.
- Introduce community-based services through peer educators.
- Strengthen ARSH clinics.
- Roll out National Iron Plus Initiative including weekly IFA supplementation.
- Promote menstrual hygiene.

**Cross Cutting Interventions**
- Bring down out of pocket expenses by ensuring JSSA, RBSK and other free entitlements.
- AMCH wings to provide specialized and quality health services.
- Health systems strengthening.
- Health demand promotion & behaviour change programs.
- Address social determinants of health care.
- Supportive supervision and use of data for monitoring and evaluation.
- Introduce difficult areas and performance based incentives.

---

**FIG. 15**
5 x 5 matrix for high impact RMNCH+A interventions
To be Implemented with High Coverage and High Quality

- Reduction in Maternal Mortality Ratio (MMR) to 100 per 100,000 live births by 2017.
- Reduction in Total Fertility Rate (TFR) to 2.1 by 2017.

---

**TABLE 14**
Coverage targets for key RMNCH+A interventions for 2017

<tr>
<td>Increase the proportion of total fertility contributed by adolescents (15-19 years) at annual rate of 3.8% per year from the baseline of 16% (NFHS-3).</td>
<td></td>
</tr>
</tbody>
</table>

---

For achieving these goals, variable increase in the coverage level for key interventions are required. These are defined in the Table 14.
While the country aims to set one collective goal towards reducing preventable maternal, newborn and child deaths by 2017, it is increasingly becoming apparent that there is varied and unequal rate of progress within the states and districts. Therefore, state specific coverage targets should be established against existing baselines. The national and state ‘scorecard’ is being introduced as a tool to increase transparency and track progress against reproductive and maternal health and child survival indicators related with intervention coverage. For more details about the scorecards please refer to page 503.

**The implementation strategies of RMNCH+A (49)**

The key interventions of RMNCH+A as a “Continuum of Care” are as shown in Fig. 16. The set of interventions are those that have high impact on reducing mortality and improving survival. Most of these interventions have been part of the previous phase of NRHM. The effectiveness of these will be determined by the coverage achieved among the affected fraction of population as also the availability, accessibility, actual utilization of services and quality of services delivered.

**Adolescent Health Programme (1, 49)**

Taking cognisance of the diverse nature of adolescent health needs, a comprehensive adolescent health strategy has been developed. The priority under adolescent health include nutrition, sexual and reproductive health, mental health, addressing gender-based violence, non-communicable diseases and substance use. The strategy proposes a set of interventions (health promotion, prevention, diagnosis, treatment and referral) across levels of care. These interventions and approaches work towards building protective factors that can help adolescents and young people develop ‘resilience’ to resist negative behaviours and operate at four major levels: individual, family, school and community by providing a comprehensive package of information, commodities and services.

The priority interventions are as follows:

1. Adolescent nutrition; iron and folic acid supplementation.
2. Facility-based adolescent reproductive and sexual health services (ARSH) (Adolescent health clinics).
3. Information and counselling on adolescent sexual reproductive health and other health issues.
4. Menstrual hygiene.
5. Preventive health check-ups.

**Clinical**

**Reproductive care**
- Comprehensive abortion care
- RTI- STI care management
- Postpartum IUCD and sterilization; interval IUCD procedures
- Adolescent friendly health services

**Pregnancy and child birth care**
- Skilled obstetric are immediate newborn care and resuscitation
- Emergency obstetric care
- Preventing Parent-to-Child Transmission (PPTCT) of HIV
- Postpartum sterilization

**Newborn and childcare**
- Essential newborn care
- Care of sick newborn, NICU, NICU
- Facility based care of children and illnesses (RMNCH),
- Care of children with severe acute malnutrition (NRC)
- Immunization

**Outreach/Sub-centre**

**Reproductive health care**
- Family planning (including IUCD insertion, OCP and condoms)
- Prevention and management of STIs
- Peri-conception folic acid supplementation

**Antenatal care**
- Full antenatal care package (PPTCT)

**Postnatal care**
- For detection and management of illnesses in mother and newborn
- Immunization

**Child health care**
- First level assessment and care for newborn and childhood illnesses
- Immunization
- Micro-nutrient supplementation

**Family & Community**

- Counselling and preparation for newborn care, breast feeding and birth preparedness
- Demand generation for pregnancy care and menstrual devices
- (JSY, JSSK)

- Home based newborn care and prompt referral
- Adolescent care for suspected case of newborn sepsis
- Intensive and Young Child Feeding (IYCF) including exclusive breast feeding and complementary feeding
- Early childhood development
- Danger sign recognition and care-seeking for illness
- Use of ORS and Zinc in case of diarrhoea

**Intersectoral**
- Water, sanitation, hygiene, nutrition, education, empowerment

**FIG. 16**

Continuum of care across life cycle and different levels of health system
A. Adolescent Reproductive and Sexual Health Programme (ARSH)

Adolescent Reproductive and Sexual Health programme (ARSH) focuses on reorganizing the existing public health system in order to meet service needs of adolescents. Steps are being taken to ensure improved service delivery for adolescents during routine sub-centre clinics and also to ensure service availability on fixed days and timings at the Primary Health Centre, Community Health Centre and District Hospital levels. Core package of services includes promotive, preventive, curative and counselling services being made available for all adolescents – married and unmarried, girls and boys through adolescent friendly health clinics. ARSH programme envisages creating an enabling environment for adolescents to seek health care services through a spectrum of programmatic approaches:

- Facility based health services—Adolescent Friendly Health Clinics;
- Counselling—Dedicated ARSH and ICTC counselling;
- Community based interventions—Outreach activities; and
- Capacity building for service providers.

i. Adolescent Friendly Health Clinics (AFHC): Through Adolescent Friendly Health Clinics, routine check-up at primary, secondary and tertiary levels of care is provided on fixed day clinics. At present 6,302 AFHCs are functional across the country providing services, information and commodities to more than 2.5 million adolescents for varied health related needs such as contraceptives provision, management of menstrual problems, RTI/STI management, antenatal care and anaemia.

ii. Facility based counselling services: Counselling services for adolescents on important issues such as nutrition, puberty, RTI/STI prevention and contraception, delaying marriage and childbearing, and concerns related to contraception, abortion services, pre-marital concerns, substance misuse, sexual abuse and mental health problems are being provided through recruitment and training of dedicated counsellors. At present 881 dedicated ARSH counsellors are providing comprehensive counselling services to adolescents across the country. In 23 States/UTs, 1439 ICTC counsellors have been enrolled to provide sexual and reproductive health counselling to adolescents.

iii. Outreach activities: Outreach activities are being conducted in schools, colleges, teen clubs, vocational training centres, during Village Health Nutrition Day (VHND), health melas and in collaboration with self help groups to provide adequate and appropriate information to adolescents in spaces where they normally congregate.

B. Weekly Iron and Folic Acid Supplementation (WIFS)

Ministry of Health and Family Welfare has launched the Weekly Iron and Folic Acid Supplementation (WIFS) Programme to meet the challenge of high prevalence and incidence of anaemia amongst adolescent girls and boys. The long term goal is to break the intergenerational cycle of anaemia, the short term benefit is of a nutritionally improved human capital. The programme, implemented across the country, both in rural and urban areas, will cover 10.25 crore adolescents. The key interventions under this programme are as follows:

- Administration of supervised weekly iron-folic acid supplements of 100 mg elemental iron and 500 µg folic acid using a fixed day approach.
- Screening of target groups for moderate/severe anaemia and referring these cases to an appropriate health facility.
- Biannual de-worming (Albendazole 400 mg), six months apart, for control of helminths infestation.
- Information and counselling for improving dietary intake and for taking actions for prevention of intestinal worm infestation.

C. Menstrual Hygiene Scheme (1)

The Ministry of Health and Family Welfare has launched the scheme for promotion of menstrual hygiene among adolescent girls in the age group of 10–19 years in rural areas. This programme aims at ensuring that girls have adequate knowledge and information about menstrual hygiene and have access to high quality sanitary napkins along with safe disposal mechanisms. Key activities under the scheme include:

- Community based health education and outreach in the target population to promote menstrual health;
- Ensuring regular availability of sanitary napkins to the adolescents;
- Sourcing and procurement of sanitary napkins;
- Storage and distribution of sanitary napkins to the adolescent girls;
- Training of ASHA and nodal teachers in menstrual health; and
- Safe disposal of sanitary napkins.

CARE DURING PREGNANCY AND CHILDBIRTH (49)

Pregnancy and childbirth are physiological events in the life of a woman. Though most pregnancies result in normal birth, it is estimated that about 15 per cent may develop complications, which cannot be predicted. Most of these complications can be averted by preventive care, skilled care at birth, early detection of risk, appropriate and timely management of obstetric complications and postnatal care.

The delivery of services during pregnancy and childbirth requires a strong element of continuum of care from community to facility level and vice versa. While the antenatal package, counselling and preparation for newborn care, breast-feeding, birth and emergency preparedness will mainly be delivered through community outreach; skilled birth attendance are to be provided at health facilities, primarily 24x7 PHC and FRU. These facilities are most likely to be the one that have been designated as “delivery points” and therefore have provision for full complement of RMNCH services. Following discharge from the health facilities, mothers and newborns will be provided postnatal care through home visits. Most of these services are already in place.

The priority interventions are as follows:

1. Delivery of antenatal care package and tracking of high-risk pregnancies.
2. Skilled obstetric care.
3. Immediate essential newborn care and resuscitation.
4. Emergency obstetric and newborn care.
5. Postpartum care for mother and newborn.
6. Postpartum IUCD and sterilization.
NEWBORN AND CHILD CARE

The interventions in this phase of life mainly focus on children under 5 years of age. Given below are the priority child health interventions that are already in place under NRHM.

**Priority Interventions (49):**

1. Home-based newborn care and prompt referral.
2. Facility-based care of the sick newborn.
3. Integrated management of common childhood illnesses (diarrhoea, pneumonia and malaria).
5. Immunization
6. Early detection and management of defects at birth, deficiencies, diseases and disability in children 0–18 years of age (Rashtriya Bal Swasthya Karyakram).

**CARE THROUGH THE REPRODUCTIVE YEARS**

Reproductive health needs to exist across the reproductive years and therefore access to these services is required in various life stages starting from the adolescence phase. Reproductive health services include the provision for contraceptives, access to comprehensive and safe abortion services, diagnosis and management of sexually transmitted infections, including HIV.

A new strategic direction has been developed for the family planning programme, wherein it has been repositioned to not only achieve population stabilisation but also to reduce maternal mortality as also infant and child mortality. A target-free approach based on unmet needs for contraception; equal emphasis on spacing and limiting methods; and promoting 'children by choice' in the context of reproductive health are the key approaches to be adopted for the promotion of family planning and improving reproductive health.

These services will be delivered at home, through community outreach and at all levels of health facilities and include adolescents and adults in the reproductive age group.

**Priority interventions (49):**

2. Promotion of spacing methods (interval IUCD).
3. Sterilization services (vasectomies and tubectomies).
4. Comprehensive abortion care (includes MTP Act).
5. Prevention and management of sexually transmitted and reproductive infections (STI/RTI).

**Delivery Points (49):**

The provision of services for delivery care in a health facility generally serves as an important indicator to assess whether the facility is optimally functional or not. The concept of 'delivery point' emerges from this presumption. Among the health facilities designated as L1, L2 and L3, there are some facilities which are conducting deliveries above a minimum bench mark (minimum 3 normal deliveries per month at L1; minimum 10 deliveries per month, including management of complications, at L2; and minimum 20–50 deliveries per month including C-section at L3). These are designated as delivery points. According to the government mandate, these facilities should be the first to be strengthened for providing comprehensive RMNCH Services. This should be supported by a referral transport system that reaches the patient within 30 minutes of receiving a call and the health facility within the next 30 minutes. The long-term goal should be to establish and operationalize Basic Emergency Obstetric Care and Comprehensive Emergency Obstetric Care Centres as per the expected delivery load in the state and district.

**Maternal and Child Health (MCH) Wing (49):**

Most health facilities, especially those at secondary and tertiary level are having high case load of pregnant women and newborn due to increase in institutional deliveries following launch of JSY and JSSK. Therefore, it has been decided that dedicated Maternal and Child Health Wings will be established in high case load facilities with adequate provision of beds. The new MCH wings will be comprehensive units (30/50/100 bedded) with antenatal waiting rooms, labour wing, essential newborn care room, SNCU, operation theatre, blood storage units and a postnatal ward and an academic wing. This will ensure provision of emergency maternal and newborn care services as well as 48 hours stay, i.e., quality postnatal care to mothers and newborns (49).

**SCORE CARD (49):**

**A. Health Management Information System - based dashboard monitoring system:**

The choice of indicators for dashboard monitoring system are based on life cycle approach, and are as shown in Fig. 17.

1. Steps underway to include proportion:
   - Pregnant women <19 yrs old to total women registered for ANC.
   - Home Based New born Care (HBNC) visit by ASHA to planned visits.
   - Children 9–11 months fully immunized children 9–11 months due for immunization.
   - Children with diarrhoea who were treated with ORS to children reported with diarrhoea.
   - Children discharged live from SNCUs to number of admissions in SNCUs.
   - Children with ARI who received treatment to children reported with ARI.

2. All India average for each indicator will be taken as the reference point.

3. States scores will be determined on the basis of the national average:
   - Positive scores from 1 to 4 for those above the national average (for positive indicators) and for those below the national average (for negative indicators).
   - Negative scores -1 to -4 for those below national average (for negative indicators).

4. All the indicator scores for each state will be consolidated as state score (all indicators have the same weightage).

5. States have been classified into four categories based on the state scores.

**B. Survey based score card (49):**

19 survey based outcome and coverage indicators related to health, nutrition and sanitation will be used for the score card. The indicators are as shown in Table 15.
HEALTH PROGRAMMES IN INDIA

Proportion of:
- 1st Trimester registration to total ANC registration
- Pregnant women received 3 ANC to total ANC registration
- Pregnant women given 100 IFA to total ANC registration
- Cases of pregnant women with obstetric complications and attended to reported deliveries
- Pregnant women receiving TT2 or Booster to total ANC registration

Proportion of:
- Postpartum sterilization to total female sterilization
- Male sterilization to total sterilization
- IUD insertions in public plus private accredited institutions to all family planning methods (IUD plus permanent)

Proportion of:
- Newborns breast-fed within 1 hour to total live births
- Women discharged in less than 48 hours of delivery in public institutions to total number of deliveries in public institutions
- Newborns weighing less than 2.5 kg to newborns weighed at birth
- Newborns visited within 24 hrs of home delivery to total reported home deliveries
- Infants 0 to 11 months old who received measles vaccine to reported live births

FIG. 17
Choice of indicators for dashboard

TABLE 15

TABLE 15

| Indicator for survey based scorecard | Latest available data from national surveys will be taken into consideration including Sample Registration System, Coverage Evaluation Survey, District Level Household and Facility Survey, National Family Health Survey, Census, Annual Health Survey. All India average for each Indicator will be taken as a reference point. States will be colour coded based on:
- Mortality indicators: nutrition, fertility. Green — less than 20% of the national average, Yellow — 20% below and above national average, Red — more than 20% of the national average.
- Remaining Indicators: Green — more than 20% of the national average, Yellow — 20% below and above the national average, Red — less than 20% of the national average.

INDIA NEWBORN ACTION PLAN (INAP)

In the past two decades, there has been remarkable progress in the survival of mother and children beyond the newborn period. Presently, the newborn health has captured the attention of the policy makers and two important milestones in this direction have been the National Rural Health Mission and the Reproductive, Maternal, Newborn, Child and Adolescent Health Strategy (RMNCH+A Strategy). RBHM has provided unprecedented attention and resources for newborn health. By adopting RMNCH+A strategy in 2013, the country observed a paradigm shift in its approach towards health care. Newborn health occupies a central stage in the overall strategy as all the inter-linkages between various components have the greatest impact on the mortality and morbidity rates of the newborn

In India, Newborn Action Plan (INAP) developed in response to the global Every Newborn Action Plan (ENAP), was launched...
in June 2014. The plan outlines a targeted strategy for accelerating the reduction of preventable newborn deaths and stillbirths in the country. INAP defines the latest evidence on effective interventions which will not only help in reducing the burden of stillbirths and neonatal mortality, but also maternal deaths. The goal is to attain “Single Digit Neonatal Mortality Rate by 2030” and “Single Digit Stillbirth Rate by 2030”.

The INAP will be implemented within the existing RMNCH+A framework, and guided by the principles of Integration, equity, gender, quality of care, convergence, accountability and partnerships. Its strength is built on its six pillars of intervention packages impacting stillbirths and newborn health, which includes: (a) Pre-conception and antenatal care; (b) Care during labour and childbirth; (c) Immediate newborn care; (d) Care of the healthy newborn; (e) Care of small and sick newborn; and (f) Care beyond newborn survival. For effective implementation, a systematic plan of monitoring and evaluation has been developed with a list of dashboard indicators (45).

The interventions under the National Health Mission focussing on newborns are shown in Table 16.

### Strategic Intervention Packages (45)

The interventions are grouped in six packages, corresponding to the various life stages of the newborn. It is estimated that high coverage of available intervention packages can prevent almost three-quarters of the newborn deaths, one-third of stillbirths and half of the maternal deaths by 2025.

The interventions have been categorized as:

a. Essential [E], to be implemented universally;
b. Situational [S], implementation dependent on epidemiological context; and

c. Advanced [A], implementation based on health-system capacity of the state/district.

The states are urged to develop their own action plans based on the six packages described below:

1. **Pre-conception and antenatal care**

Health interventions must start well before conception and their impact on the neonatal and stillbirth outcome requires equivalent consideration. The importance of antenatal care for improved neonatal and perinatal outcome...
Bea HEALTH PROGRAMMES IN INDIA is well established; however, coverage of a few salient interventions needs increased attention (e.g., use of long-lasting insecticide treated nets and intermittent preventive treatment of malaria, antenatal syphilis screening combined with treatment and increased emphasis on early detection, and prompt treatment of complications in pregnancy such as pre-eclampsia, type-2 diabetes).

The strategic interventions for pre-conception and antenatal care for newborns are given below.

Pre-conception and antenatal care interventions package

1. Reproductive health & family planning [E]
   - Adolescent reproductive health
   - Delaying age of marriage and first pregnancy
2. Nutrition related interventions [E]
   - Balanced energy protein supplementation
   - Pre-conceptional folic acid
   - Maternal calcium supplementation
   - Multiple micronutrient supplementation (Iron, folic acid and iodine)
   - Nutrition counselling
3. Counselling and birth preparedness [E]
4. Prevention against malaria [S]

Outreach/Sub-centre

5. Antenatal screening for anaemia and hypertensive disorders of pregnancy (PIH, pre-eclampsia, eclampsia) [E]
6. Antenatal screening for malaria [S]
7. Prevention and management of mild to moderate anaemia [E]
8. Maternal tetanus immunization [E]
9. Adolescent friendly health services (nutrition and reproductive health counselling) [E]
10. Interval IUCD insertion [E]
11. Adolescent friendly health clinics (as per RKSK guidelines) [E]

Health facility

1. Antenatal corticosteroids in preterm labour [E]
2. Antibiotics for premature rupture of membranes [E]
3. Fetal heart monitoring in labour [E]
4. PPHNICD insertion [E]
5. Prevention of Rh disease using anti D immunoglobulin [S]

2. Care during labour and childbirth

Intra-partum complications and preterm births remain a challenge to the neonatal survival. Care during labour and childbirth have the potential to reduce stillbirths by a third. It is important to emphasize that BEmOC can reduce intrapartum-related neonatal deaths by 40% and CEmOC can also reduce newborn mortality by 40%, whereas skilled attendance at birth alone without access to the emergency component has a smaller effect at 25%. Care at childbirth also has additional benefits on child survival, improved growth, reduced disability and non-communicable diseases.

Antenatal corticosteroids use to manage preterm labour not only reduces neonatal deaths by 31%, but this intervention is also associated with reduced need of specialized care for newborns, such as ventilators, etc. Antibiotics administration for pre-mature rupture of membranes (PROM) reduces early-onset postnatal sepsis. Clean birth practices especially hand-washing with soap and water by birth attendant has been found to reduce mortality due to sepsis in births at home (15%), facilities (27%), and during postnatal period (40%).

The strategic interventions for care during labour and childbirth are given below:

Immediate newborn care

Immediate care is the basic right of every newborn baby. This package includes interventions such as immediate drying and stimulation, provision of warmth, hygienic care, early initiation of breast-feeding, and administration of vitamin K. For babies who do not breathe at birth, neonatal resuscitation is a crucial life-saving intervention. Resuscitation training of providers in facilities reduces intrapartum-related neonatal deaths and early neonatal deaths substantially. Hypothermia is a risk factor for neonatal mortality, especially in cases of preterm and low birth weight babies. All steps should be taken to prevent and manage hypothermia, and rooming-in of babies with mother must be universally practiced. Delayed cord clamping in newborns, including pre-term babies is associated with decreased risk of anaemia and intraventricular haemorrhage. Administration of vitamin K at birth prevents haemorraghic disease of newborn.

The strategic interventions for immediate newborn care are given below:

Immediate newborn care

Family and community

1. Skilled birth attendance [E]
2. Clean birth practices [E]

Outreach/Sub-centre

3. Identification of complications and timely referral [E]
4. Pre-referral dose by ANM [E]:
   - Antenatal corticosteroids in preterm labour
   - Antibiotics for premature rupture of membranes

Health facility

5. Emergency obstetric care [E]:
   - Basic and comprehensive
6. Management of preterm labour [E]:
   - Antenatal corticosteroids in preterm labour
   - Antibiotics for premature rupture of membranes

3. Immediate newborn care

Immediate newborn care

Family and community

1. Delayed cord clamping [E]
2. Interventions to prevent hypothermia [E]
   - Immediate drying
   - Head covering
   - Skin-to-skin care
   - Delayed bathing
3. Early initiation and exclusive breast-feeding [E]
4. Hygiene to prevent infection [E]

Outreach/Sub-centre

5. Vitamin K at birth [E]
6. Neonatal resuscitation [E]

Health facility

7. Advanced neonatal resuscitation [E]
4. Care of healthy newborn

Evidence shows that community-based interventions can significantly improve child survival. A large number of ASHAs have been trained to perform various preventive and promotive health activities, such as counselling of mothers on breast-feeding, complementary feeding, immunization, care-seeking, promoting nutrition, sanitation, and safe drinking water, etc. Despite the significant increase in institutional deliveries, home deliveries persist to about 25% to 40% in pockets across states. Even in cases of institutional deliveries, most women tend to return home within a few hours after delivery. For women who stay at the institution for 48 hours or more, it is also important to provide care to the neonate at home for the remaining critical days of the first week and up to the 42nd day of life. Home visitation by ASHAs can contribute significantly to delivery of interventions with focus on the newborn period. Regular and timely contacts with the newborn are essential for ensuring continued exclusive breast-feeding, appropriate immunization, and care-seeking of children with danger signs.

The interventions for care of healthy newborn are given below:

<table>
<thead>
<tr>
<th>Family and community</th>
</tr>
</thead>
<tbody>
<tr>
<td>1. Home visits till six weeks by trained ASHA [E] :</td>
</tr>
<tr>
<td>- Counselling</td>
</tr>
<tr>
<td>- Prevention of hypothermia, cord care</td>
</tr>
<tr>
<td>- Early identification of danger signs</td>
</tr>
<tr>
<td>- Prompt and appropriate referral</td>
</tr>
<tr>
<td>2. Exclusive breast-feeding [E]</td>
</tr>
<tr>
<td>3. Clean postnatal practices [E]</td>
</tr>
<tr>
<td>Outreach/Sub-centre</td>
</tr>

</tr>
<tr>
<td>- OPV</td>
</tr>
<tr>
<td>- Hepatitis B</td>
</tr>
<tr>
<td>- DPT</td>
</tr>
<tr>
<td>Health facility</td>
</tr>
<tr>
<td>All the interventions (except home visits)</td>
</tr>
</tbody>
</table>

5. Care of small and sick newborn

Specific interventions for small and sick newborns include Kangaroo mother care (KMC). KMC involves package of early and continuous skin-to-skin contact, breast-feeding support, and supportive care in stable newborns weighing less than 2000 gm. KMC can be practiced even at home, thus improving chances of newborn survival.

Strategic interventions for care of small and sick newborn include :

<table>
<thead>
<tr>
<th>Care of small and sick newborn</th>
</tr>
</thead>
<tbody>
<tr>
<td>Family and community</td>
</tr>
<tr>
<td>1. Thermal care and feeding support (for home deliveries) [E]</td>
</tr>
<tr>
<td>Outreach/Sub-centre</td>
</tr>
<tr>
<td>2. Integrated management using IMNCI and use of oral antibiotics [E]</td>
</tr>
</tbody>
</table>
| 3. Injectable Gentamicin by ANMs for sepsis [E] :
  - Pre-referral |
  - Completion of antibiotic course in case referral is refused, not possible “OR” as advised by treating physician |
| Health facility |
| 4. Kangaroo mother care at facility [E] |
| 5. Full supportive care at block and district level [E] :
  - NBSU at block level |
  - SNCU at district level |
| 6. Intensive care services (NICU) at regional level [A] for ~
  - Assisted ventilation |
  - Surfactant use |
  - Surgery |

6. Care beyond newborn survival

This is a new package considering the burden of birth defects and developmental delays in newborns. It is of particular significance for SGA and preterm newborns, as well as newborns discharged from SNCUs.

The table below lists the interventions to care for newborns beyond their survival.

<table>
<thead>
<tr>
<th>Care beyond newborn survival</th>
</tr>
</thead>
<tbody>
<tr>
<td>Family and community</td>
</tr>
<tr>
<td>1. Screening for birth defects, failure to thrive and developmental delays [E]</td>
</tr>
</tbody>
</table>
| 2. Follow-up visits of [E] :
  - SNCU discharged babies till 1 year of age |
  - Small and low birth weight babies till 2 years of age |
| Outreach/Sub-centre |
| 3. As before |
| Health facility |
| 4. Newborn screening [A] |
| 5. Management of birth defects [E] :
  - Diagnosis |
  - Treatment, including surgery |
| 6. Follow-up of high-risk infants (discharged from SNCUs and small newborns) for ~
  - Developmental delay |
  - Appropriate management |
Monitoring and Evaluation (45)

A comprehensive assessment of targets would be done in 2020, which will help plan course corrections, if any, in on-going interventions. Further, from the year 2020, the milestones will be reviewed every five years keeping in sync with ENAP — i.e., 2025, 2030, and 2035.

Following core indicators (dashboard indicators) have been selected for monitoring, based on direct relevance to the action plan framework, targets, goals, and review of current data availability.

NATIONAL PROGRAMME FOR HEALTHCARE OF THE ELDERLY (NPHCE) (6)

Government of India has launched the "National Programme for Health Care of the Elderly" (NPHCE) to address health related problems of elderly people, in 100 identified districts of 21 states during the 11th Plan period. 8 regional geriatric centres as referral units have also been developed in different regions of the country under the programme.

The basic aim of the NPHCE Programme is to provide separate, specialized and comprehensive healthcare to the elderly without compromising the right to the senior citizens at various level of state healthcare delivery system including outreach services. Preventive and promotive care, management of illness, health manpower development for geriatric services, medical rehabilitation and therapeutic intervention and Information Education & Communication (IEC) are some of the strategies envisaged in the NPHCE.

It is expected to cover other districts in a phased manner. 12 regional geriatric centres in selected medical colleges of the country are expected to be developed under the programme. In addition, 2 National Centre of Ageing (NCA) are being established at AIIMS New Delhi and Madras Medical College, Chennai, the core functions of which are training of health professionals, research activity and healthcare delivery in the field of geriatrics.

The details of the geriatric setup and activities undertaken so far under the programme at various healthcare levels are as below (7):
Department of Geriatric at 20 Super Specialized Institutions: Geriatric Departments are being developed at 8 identified medical institution located in various regions of the country with 30 bedded in patient facility. Apart from providing referral treatment, research and manpower development, these institutions are involved in developing and updating training materials for various levels of health functionaries, developing IEC material, guidelines, etc. Funds have been provided for manpower, equipments, medicines, construction of building, training etc.

Geriatric unit at district hospitals: The programme is approved for implementation in 2017-2018 in 520 districts, covering 35 states. There is provision for establishing 10 bedded geriatric ward and dedicated OPD services exclusively for geriatric patients. The grant-in-aid has been provided for contractual manpower, equipments, medicines, construction of building, training etc.

Rehabilitation Units at CHCs falling under identified districts: There is provision for dedicated health clinics for the elderly persons twice a week. A rehabilitation unit is being set up at all the CHCs falling under identified districts. The grant-in-aid has been provided for manpower, equipments, training. The rehabilitation worker is supposed to provide physiotherapy to the needy elderly persons.

Activity at PHCs under identified districts: Weekly geriatric clinics are arranged at the identified PHCs by a trained Medical Officer. For diseases needing further investigation and treatment, persons will be referred to the first referral unit i.e. the Community Health Centre or District Hospital as per need. A one-time grant is given to PHCs for procurement of equipment.

Activity at Sub-centre under districts: The ANMs/Male Health Workers posted in sub-centre will make domiciliary visits to the elderly persons in area under their jurisdiction. She/he will arrange suitable calipers and supportive devices from the PHC and provide the same to the elderly disabled persons to make them ambulatory. Also, there will be a provision for treatment of minor ailments and rehabilitation equipment at the sub-centre as per need.

The tertiary component of the programme has been renamed as “Rashtriya Varishth Jan Swasthya Yojna” (RVJSY).

NATIONAL PROGRAMME FOR PREVENTION AND CONTROL OF CANCER, DIABETES, CARDIOVASCULAR DISEASES AND STROKE (NPCDCS)

India is experiencing a rapid health transition with large and rising burden of chronic non-communicable diseases (NCDs) especially cardiovascular disease, diabetes mellitus, cancer, stroke, and chronic lung diseases. It is estimated that in 2016 NCDs accounted for 60 per cent of deaths. Considering the fact that NCDs are surpassing the burden of communicable diseases in India and the existing health system is mainly focussed on communicable diseases, need for National Programme on Prevention and Control of Diabetes, Cardiovascular Diseases and Stroke was envisaged. Later on this programme was integrated with National Cancer Control Programme, and National Programme for Prevention and Control of Cancer, Diabetes, Cardiovascular Diseases and Stroke (NPCDCS) came into existence. During the 11th Five Year Plan period, 100 identified districts in 21 states have been covered under the programme. During 12th Five Year Plan, the programme has covered all the districts of the country in a phased manner (7).

A. Diabetes, Cardiovascular Disease and Stroke (DCS) Component under NPCDCS

The programme focuses on the health promotion, capacity building including human resource development, early diagnosis and management of these diseases with integration with the primary health care system.

The major objectives of the programme are as follows (7):
- Prevent and control common NCDs through behaviour and lifestyle changes
- Provide early diagnosis and management of common NCDs
- Build capacity at various levels of health care for prevention, diagnosis and treatment of common NCDs
- Train human resource within the public health set-up by doctors, paramedics and nursing staff to cope with the increasing burden of NCDs, and
- Establish and develop capacity for palliative & rehabilitative care.

The programme is to be implemented in 20,000 sub-centres and 700 community health centres (CHCs) in 100 districts across 21 States/UTs and the strategies include promoting healthy lifestyle through massive health education and mass media efforts at country level, opportunistic screening of persons above the age of 30 years, establishment of Non-Communicable Disease (NCD) Clinic at Community Health Centre (CHC) and District level, development of trained manpower and strengthening of tertiary level health facilities. For long-term sustainability of the programme, service delivery will be through existing public health infrastructure and systems. The various approaches such as mass media, community education and interpersonal communication will be used for behavioural change focusing on the following messages:
- Increased intake of healthy foods
- Increased physical activity
- Avoidance of tobacco and alcohol
- Stress management.

Activities at Sub-Centre

Health promotion for behaviour and lifestyle change will be carried out by organizing various camps, interpersonal communications, posters, banners, etc. Opportunistic screening of population above 30 years will be carried out using BP measurement and blood glucose by strip method. The suspected cases of diabetes and hypertension will be referred to CHCs of higher health facility for further diagnosis and management. For screening of diabetes, glucometer optium xceed, optium test strips and auto disabled lancets are being procured at central level and provided to the concerned states as per their requirements from time to time.

Activities at CHC

NCD clinic at CHC shall do the diagnosis by required investigations/test like blood sugar measurement, lipid profile, ultrasound, X-ray and ECG etc., management and stabilization of common CVD, diabetes and stroke cases (out-patient as well as in-patients). One of the nurses appointed under the programme shall undertake home visits
for bedridden cases, supervise the work of health workers and attend monthly clinics being held in the villages on a random basis. Complicated cases of diabetes, high blood pressure etc. shall be referred from CHC to the district hospital for further investigations and management.

**Activities at district hospital**

NCD clinic at district hospital shall screen persons above the age of 30 years for diabetes, hypertension, cardiovascular diseases etc. to identify individuals who are at a high-risk of developing diabetes, hypertension and CVDs warranting further investigation/action. Detailed investigation will be done in respect of persons those who are at high-risk of developing NCDs on screening and those who are referred from CHCs. They shall provide regular management and annual assessment of persons suffering from cancer, diabetes and hypertension. People with established cardiovascular diseases shall also be managed at district hospital. They shall provide home based palliative care for chronic, debilitating and progressive patients. Apart from clinical services, district hospital shall be involved in promotion of healthy lifestyle through health education and counselling to the patients and their attendants.

**Urban health check-up scheme for diabetes and high blood pressure**

The scheme has the following objectives:

1. To screen urban slum population for diabetes and high blood pressure
2. To create database for prevalence of diabetes and high blood pressure in urban slums.
3. To sensitize the urban slum population about healthy lifestyle.

The blood sugar and blood pressure will be checked for all ≥30 years and all pregnant women of all age.

The NCD cells at the centre, state and district will implement and monitor the National Programme for Prevention and Control of Cancer, Diabetes, CVD and Stroke (NPCDCS) in various states. The national NCD cell has been established at the centre.

**Achievements under the programme**

As on 30th September 2015, the programme is under implementation in all 36 states/UTs. The facilities available are as shown in Table 17.

Source: (6)

**New initiatives under the programme**

1. Intervention for prevention and control of Rheumatic Heart Disease under NPCDCS and Rashtriya Bal Swasthya Karyakram (RBSK).
2. Integration of AYUSH with NPCDCS.
3. Integration of RNTCP with NPCDCS to articulate a national strategy for management of TB and diabetes comorbidities in India

**Guidelines for referral and treatment** (62)

Government of India has developed operational guidelines (2016) for prevention, screening and control of common noncommunicable diseases. The guidelines for referral, treatment and for ensuring the continuity of care are as follows:

1. Those with a systolic blood pressure of over 140 and a diastolic blood pressure of over 90 mm of Hg, or random blood sugar of 140 mg/dl and above would be referred to a medical officer, at the nearest facility, for confirmation, conducting relevant laboratory investigations and initiation of treatment.
2. Those who are found positive for cancer/precancerous lesions will be referred by ANM/Staff Nurse in specified screening sites to the appropriate PHC/CHC/District Hospital for confirmation and treatment by trained specialist, as per the operational framework developed for cancer screening and management.
3. Once the diagnosis of Hypertension/diabetes is established, the patient must receive at least a month’s supply of drugs from the PHC. Once the condition is stable, the state could also decide to provide the patient with a three-month supply, with the ANM/ASHA visiting the patient each month for ensuring compliance, checking on diet and lifestyle modification, and measuring the blood pressure/blood glucose. Alternatively, a three-month drug supply could be stocked with the ANM at sub-centre, to be given each month. Either way, sufficient drug supplies need to be made available at the PHC.
4. The patient will need to go the PHC for the first follow up at the end of the first three months after diagnosis, and sooner if required. An annual specialist consultation at the nearest nodal CHC with NCD clinic, is also recommended, based on the decision of the MO at the PHC.
5. For those individuals who are already on treatment under the care of a private practitioner, they could be offered the choice of taking drugs from the public health system, after appropriate confirmation. However, these individuals would be visited regularly by the frontline workers, monitored for compliance with treatment/lifestyle changes and recorded in the health card.
6. Community Follow up of these individuals would be by the ASHA making visits to enable positive behaviour modifications, treatment compliance, and encouraging patients to go the sub-centre for regular check-up of BP/blood glucose. Some states have also provided the ASHA with BP apparatus and glucometers to undertake regular examinations at the village level. The ASHA will prioritize those households where there are treatment defaulters or those who experience complications. The aim is to minimize treatment defaulters and to achieve hypertension and glycaemic control at an individual and population level. The ANM would also conduct regular home visits.

WHO has developed a comprehensive global monitoring framework for prevention and control of NCDs (2013-2020), which was endorsed by World Health Assembly in May 2013. This includes nine voluntary targets to monitor the progress made in the implementation of the programme. India is committed to implementation of the action plan and take necessary steps to meet the objectives. The indicators and targets are as shown in Table 18 (63).

**B. Cancer component under NPCDCS**

Cancer is an important public health problem in India, with nearly 10 lakh new cases occurring every year in the country. It is estimated that there are 2.8 million cases of cancer in the country at any given point of time. With the objectives of prevention, early diagnosis and treatment, the national cancer control programme was launched in 1975-76. In view of the magnitude of the problem and gaps in the availability of cancer treatment facilities across the country, the programme was revised in 1984-85 and subsequently in December 2004. During 2010, the programme was integrated with National Programme on Prevention and Control of Diabetes, Cardiovascular Disease and Stroke. The objectives of the programme are:

a. Primary prevention of cancers by health education;
b. Secondary prevention i.e. early detection and diagnosis of common cancer such as cancer of cervix, mouth, breast and tobacco related cancer by screening/self examination method; and
c. Tertiary prevention i.e. strengthening of the existing institutions of comprehensive therapy including palliative care.

The schemes under the revised programme are:

1. **Regional Cancer Centre Scheme**

The existing regional cancer centres are being further strengthened to act as referral centres for complicated and difficult cases at the tertiary level. One time assistance of Rs. 3 crores during the plan period is provided to Regional Cancer Centres except TMH, Mumbai and IRCH (AIIMS) for strengthening and to the CNCI, Kolkata on the approved pattern of funding.

2. **Oncology Wing Development Scheme**

This scheme had been initiated to fill up the geographic gaps in the availability of cancer treatment facilities in the country. Central assistance is provided for purchase of equipment, which include a cobalt unit besides other equipment. A part of the grant can be used for the civil work but the manpower is to be provided by the concerned state government/institution. The quantum of central assistance is Rs. 3 crores per institution under the scheme.

3. **Decentralized NGO scheme**

This scheme is meant for IEC activities and early detection of cancer. The scheme is operated by the nodal agencies and the NGOs are given financial assistance for undertaking health education and early detection activities of cancer.

4. **IEC activities at central level**

IEC activities at the central level are to be initiated in order to give wider publicity about the Anti Tobacco Legislation for discouraging consumption of cigarettes and other tobacco related products, and for creating awareness among masses about the ill effects of consumption of tobacco and tobacco related products. Under this scheme wider publicity would also be given about the rules being formulated for implementation of various provisions of the anti-tobacco legislation. November 7th is observed as National Cancer Awareness Day in the country.

5. **Research and training**

Training programmes, monitoring and research activities will be organized at the central level under this scheme. Following training manuals have been developed under the NCCP for capacity building in cancer control at district level:

- a. Manual for health professionals
- b. Manual for cytology
- c. Manual for palliative care
- d. Manual for tobacco cessation
Cancer services under national programme for prevention and control of cancer, diabetes, CVD and stroke (43):  

1. Common diagnostic services, basic surgery, chemotherapy and palliative care for cancer cases is being made available at 100 district hospitals.  
2. Each district is being supported with Rs. 1.66 crores per annum for the following:  
   - Chemotherapy drugs are provided for 100 patients at each district hospital.  
   - Day care chemotherapy facilities is being established at 100 district hospitals.  
   - Facility for laboratory investigations including mammography is being provided at 100 district hospitals and if not available, this can be outsourced at government rates.  
3. Home based palliative care is being provided for chronic, debilitating and progressive cancer patients at 100 districts.  
4. Support is being provided for contractual manpower through 1 Medical Oncologist, 1 Cytopathologist, 1 Cytopathology technician, 2 Nurses for day care.  
5. State Cancer Institutes will provide comprehensive cancer diagnosis, treatment and care services. SCI will be apex institution in the state for cancer treatment activities.  
6. 45 centres were to be strengthened as Tertiary Cancer Centres (TCCs) to provide comprehensive cancer care services at a cost of Rs. 6.00 crore each during 2011–12.  

**TOBACCO CONTROL LEGISLATION (64)**  
A comprehensive tobacco control legislation titled “The Cigarettes and other Tobacco Products (Prohibition of Advertisement and Regulation of Trade and Commerce, Production, Supply and Distribution) Act, 2003” was passed by the parliament in April, 2003 and notified in Gazette of India on 25th Feb, 2004. The important provisions of the Act are:  

- Prohibition of smoking in public places:  
- Prohibition of direct and indirect advertisement of cigarette and other products:  
- Prohibition of sale of cigarette and other tobacco products to a person below the age of 18 years:  
- Prohibition of sale of tobacco products near the educational institutions:  
- Mandatory depiction of statutory warnings (including pictorial warnings) on tobacco packs; and  
- Mandatory depiction of tar and nicotine contents along with maximum permissible limits on tobacco packs.  

The rules related to prohibition of smoking in public places came into force from the 2nd October, 2008. As per rules, it is mandatory to display smoke free signages at all public places. Labelling and packaging rules mandating the depiction of specified health warnings on tobacco product packs came into force from 31st May, 2009.  

On account of sustained efforts on the part of Ministry of Health and Family Welfare, 34 States/UTs have issued orders for implementation of the Food Safety Regulations banning manufacture, sale and storage of gutka and pan masala containing tobacco or nicotine in the year 2014–15. Besides several states/UTs have banned all forms of smokeless tobacco products such as chewing tobacco, zarda, khaini and other flavoured and processed tobacco irrespective of name and form (6).  

On 24th September 2015, Government of India notified that the rules on “tobacco pack pictorial warnings” would come into effect from 1st April 2016. These rules mandate display of pictorial health warnings on 85 per cent of the principle display area of tobacco product pack on both sides (60 per cent of the picture and 25 per cent of the text).  

**National Tobacco Control Programme (3)**: In order to facilitate the implementation of the Tobacco Control Laws, to bring about greater awareness about the harmful effects of tobacco, and to fulfill the obligations under the WHO-Framework convention on tobacco control, Govt. of India has launched a new National Tobacco Control Programme in the 11th Five Year Plan. Pilot phase was launched in 16 districts covering 9 states in 2007-08. It now covers 108 districts in 31 states in the country. The main components of the programme are:  

1. Public awareness/mass media campaigns for awareness building and for behavioural change:  
2. Establishment of tobacco product testing laboratories, to build regulatory capacity, as required under COTPA, 2003;  
3. Mainstreaming the programme components as a part of the health delivery mechanism under the NRHM framework:  
4. Mainstream research and training on alternate crops and livelihood, with other nodal ministries:  
5. Monitoring and evaluation, including surveillance, e.g. adult tobacco survey:  
6. Dedicated tobacco control cells for effective implementation and monitoring of anti-tobacco initiatives:  
7. Training of health and social workers, NGOs school teachers etc:  
8. School programme; and  

**NATIONAL MENTAL HEALTH PROGRAMME**  
The National Mental Health Programme was launched during 1982 with a view to ensure availability of Mental Health Care Services for all, especially the community at risk and underprivileged section of the population, to encourage application of mental health knowledge in general health care and social development. A National Advisory Group on mental health was constituted under the Chairmanship of the Secretary, Ministry of Health and Family Welfare for the effective implementation of the National Health Programme. Eleven institutions have been identified for imparting training in basic knowledge and skills in the field of mental health to the primary health care physicians and paramedical personnel. At present this programme covers 517 districts in 36 states.  

The aims of the NMHP are: (a) Prevention and treatment of mental and neurological disorders and their associated disabilities; (b) Use of mental health technology to improve general health services; and (c) Application of mental health principles in total national development to improve quality of life (65).  

The objectives of the programme are:  

1. To ensure availability and accessibility of minimum mental health care for all in the foreseeable future, particularly to the most vulnerable and underprivileged sections of population.  
2. To encourage application of mental health knowledge in general health care and in the social development.
3. To promote community participation in the mental health services development, and to stimulate efforts towards self-help in the community.

The programme strategies are:

1. Integration of mental health with primary health care through the NMHP;
2. Provision of tertiary care institutions for treatment of mental disorders;
3. Eradicating stigmatization of mentally ill patients and protecting their rights through regulatory institutions like the Central Mental Health Authority, and State Mental Health Authority.
4. Training programmes of all workers in the mental health team at the identified nodal institute in the state;
5. Public education in mental health to increase awareness and to valorise data and experience at the level of community to service and research.

District Mental Health Programme components are:

(a) Training programmes of all workers in the mental health team at the identified nodal institute in the state; (b) Public education in mental health to increase awareness and to reduce stigma; (c) For early detection and treatment, the OPD and Indoor services are provided; and (d) Providing valuable data and experience at the level of community to the state and centre for future planning, improvement in service and research.

District Mental Health Programme has now incorporated promotive and preventive activities for positive mental health which includes:

- School mental health services: Life skills education in schools, counselling services
- College counselling services: Through trained teachers/counsellors
- Workplace stress management: Formal & Informal sectors, including farmers, women etc.
- Suicide prevention services: Counselling center at district level, sensitization workshops, IEC, help lines etc.

The National Human Rights Commission also monitors the conditions in the mental hospitals along with the government of India, and the states are acting on the recommendations of the joint studies conducted to ensure quality in delivery of mental care.

Thrust areas (43)

1. District mental health programme in an enlarged and more effective form covering the entire country.
2. Streamlining/modernization of mental hospitals in order to modify their present custodial role.
3. Upgrading department of psychiatry in medical colleges and enhancing the psychiatric content of the medical curriculum at the undergraduate as well as postgraduate level.
4. Strengthening the central and state mental health authorities with a permanent secretariat. Appointment of medical officers at state headquarters in order to make the monitoring role more effective.
5. Research and training in the field of community mental health, substance abuse and child adolescent psychiatric clinics.

The Mental Healthcare Act, 2017 (7)

The United Nations convention on the rights of persons with disabilities was ratified by the Government of India thus making it obligatory on the Government to align the policies and laws of the country with the convention. There was an increasing realization that persons with mental illness constitute a vulnerable section of society and are subject to discrimination in our society.

The Mental Healthcare Bill, 2013 was introduced in the Parliament in order to protect and promote the rights of persons with mental illness during the delivery of health care in institutions and in the community and to ensure health care, treatment and rehabilitation of persons with mental illness, is provided in the least restrictive environment possible. Further, to regulate the public and private mental health sectors within a rights framework, to achieve the greatest public health good and to promote principles of equity, efficiency and active participation of all stakeholders in decision making. Suicide has been decriminalized under the Act. The bill received assent of the Hon'ble President of India on 07.04.2017. The Ministry has constituted a committee of experts for formulating rules and regulations under the Act.

**INTEGRATED DISEASE SURVEILLANCE PROJECT**

Integrated disease surveillance project is a decentralized state based surveillance system in the country. This project is intended to detect early warning signals of impending outbreaks and help initiate an effective response in a timely manner in urban and rural areas. It will also provide essential data to monitor progress of ongoing disease control programme and help allocate health resources more efficiently. The project was launched in Nov. 2004. It was a 5 year project up to March 2010. The project was restructured and extended up to March 2012. It continues in the 12th Five Year Plan with domestic budget as Integrated Disease Surveillance Programme under National Health Mission for all states.

A Central Surveillance Unit (CSU) established and integrated in the National Centre for Disease Control, Delhi, State Surveillance Units (SSU) at all State/UT head quarters and District Surveillance Units (DSU) at all districts in the country have been established. IT network connecting 776 sites in states/district head quarters and premier institutes has been established with the help of National Information Centre and ISRO (Indian Space Research Organization) for data entry, training, video conferencing and outbreak discussions.

Under the project weekly disease surveillance data on epidemic prone diseases are being collected from reporting units such as sub-centres, PHCs, CHCs, hospitals including government and private sector hospitals and medical colleges. The data are being collected on 'S' syndromic; 'P' probable; and 'L' laboratory formats using standard case definitions. Presently more than 90 percent districts report such weekly data through e-mail/portals. The weekly data are analysed by SSU/DSU for disease trends. Whenever there is rising trend of illness, it is investigated by the Rapid Response Team to diagnose and control the outbreak. It is a multi-speciality team of an epidemiologist, a clinician, a microbiologist and other specialists as per requirement.

The surveillance is needed to recognize cases or cluster of cases to initiate interventions to prevent transmission of disease or reduce morbidity and mortality; access the public health impact of health events or determine and measure trends; demonstrate the need for public health intervention programmes and resources and allocate resources during public health planning; monitor effectiveness of prevention and control measures; identify high-risk groups or geographical areas to target interventions and guide analytic studies; and develop hypothesis that lead to analytic studies about risk factors for disease causation, propagation and progression (66).
In this project, different types of integration are proposed. These include: (a) Sharing of surveillance information of disease control programmes; (b) Developing effective partnership with health and non-health sectors in surveillance; (c) Including non-communicable and communicable diseases in the surveillance system; (d) Effective partnership of private sector and NGOs in surveillance activities; and (e) Bringing academic institutions and medical colleges into the primary public health activity of disease surveillance.

The important information in disease surveillance are — who gets the disease, how many get the disease, where did they get the disease, why did they get the disease, and what needs to be done as public health response.

The components of the surveillance activity are:
(a) Collection of data
(b) Compilation of data
(c) Analysis and interpretation
(d) Follow-up action
(e) Feedback.

The prerequisite of the effective surveillance are — use of standard case definition, ensure regularity of reports and the action on reports.

The classification of surveillance in IDSP is as follows:

(a) Syndromic diagnosis — diagnosis is made on the basis of clinical pattern by paramedical personnel and members of the community;
(b) Presumptive diagnosis — diagnosis made on typical history and clinical examination by medical officer; and
(c) Confirmed diagnosis — clinical diagnosis by a medical officer and or positive laboratory identification

 Syndromes under surveillance (66):
The paramedical health staff will undertake disease surveillance based on broad categories of presentation. The following clinical syndromes will be under surveillance in IDSP:
1. Fever:
   a. Less than 7 days duration without any localizing signs
   b. With rash
   c. With altered sensorium or convulsions
   d. Bleeding from skin or mucus membrane
   e. Fever more than 7 days with or without localizing signs
2. Cough more than 3 weeks duration
3. Acute flaccid paralysis
4. Diarrhoea
5. Jaundice, and
6. Unusual events causing death or hospitalization.

These syndromes are intended to pick up all priority diseases listed under regular surveillance at the level of the community under the Integrated Disease Surveillance Project.

Diarrhoea
Jaundice

Unusual syndromes

The core conditions under surveillance in IDSP are as follows (68):

(i) Regular Surveillance:

![](Image)

(ii) Sentinel Surveillance:

- Sexually transmitted diseases / blood borne
- Other conditions

(iii) Regular periodic surveys:

- NCD risk factors
- Other international commitments

(iv) Additional state priorities:

Each state may identify up to five additional conditions for surveillance.

**Outbreak**

In epidemiology, an outbreak is a sudden increase in occurrence of a disease in a particular time and place. A single case of a communicable disease long absent from a population, or caused by an agent (e.g., bacterium or virus) not previously recognized in that community or area, or emergence of a previously unknown disease, may also constitute an outbreak and should be reported and investigated.

Warning signs of an impending outbreak are as follows (67):
- Clustering of cases or deaths in time and/or space
- Unusual increase in number of cases or deaths
- Even a single case of measles, AFP, cholera, plague, dengue or JE
- Acute febrile illness of unknown aetiology
- Occurrence of two or more epidemiologically linked cases of meningitis, measles
- Unusual isolate
- Shifting in age distribution of cases
- Sudden increase/high vector density
- Natural disasters

Summary of outbreak syndromes and trigger events for investigation (67):

<table>
<thead>
<tr>
<th>Syndrome</th>
<th>Trigger event</th>
</tr>
</thead>
<tbody>
<tr>
<td>Acute watery stools</td>
<td>- A single case of severe dehydration/death in a patient &gt; 5 years of age with diarrhoea.</td>
</tr>
<tr>
<td></td>
<td>- More than 10 houses having at least one case of loose stools irrespective of age, per village or an urban ward.</td>
</tr>
<tr>
<td>Fever &lt; 7 days duration</td>
<td></td>
</tr>
<tr>
<td>(a) Only fever</td>
<td>5 cases in 1000 population.</td>
</tr>
<tr>
<td>(b) With rash (Measles / Dengue)</td>
<td>Two similar cases in a village (1000 population).</td>
</tr>
<tr>
<td>(c) Altered consciousness</td>
<td>Two cases of fever with altered consciousness in the village/1000 population.</td>
</tr>
<tr>
<td>(d) Fever with bleeding</td>
<td>Two cases of fever with bleeding in a village or 1000 population.</td>
</tr>
<tr>
<td>Fever with convulsions</td>
<td>Two cases of fever with convulsions in a village or 1000 population.</td>
</tr>
<tr>
<td>Fever more than 7 days</td>
<td>More than 2 cases in a village 1000 population.</td>
</tr>
<tr>
<td>Jaundice</td>
<td>More than 2 cases in a village or in 1000 population.</td>
</tr>
<tr>
<td>Unusual event</td>
<td>More than 2 deaths or hospitalization.</td>
</tr>
</tbody>
</table>

The reporting units for disease surveillance are:

<table>
<thead>
<tr>
<th>Public Health Sector</th>
<th>Private Health Sector</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rural</td>
<td></td>
</tr>
<tr>
<td>CHCs</td>
<td>Sentinel private practitioners and Sentinel hospitals</td>
</tr>
<tr>
<td>District hospitals</td>
<td></td>
</tr>
<tr>
<td>Urban</td>
<td></td>
</tr>
<tr>
<td>ESI Railway</td>
<td>Sentinel private nursing homes, Sentinel hospitals</td>
</tr>
<tr>
<td>Medical college hospitals</td>
<td>Medical colleges, Private and NGO laboratories</td>
</tr>
</tbody>
</table>

1. Sub-centre—health worker/ANM reports all patients fulfilling the clinical syndrome from PHC, private clinic, hospital etc.
2. PHC/CHC medical officers report as probable cases of interest, where this cannot be confirmed by laboratory tests at the peripheral reporting units, and as confirmed when the laboratory information is available as in case of blood smear +ve malaria and sputum AFB +ve tuberculosis.
3. Sentinel private practitioners, district hospitals, municipal hospitals, medical colleges, sentinel hospitals, NGOs – medical officers report as probable cases of interest.

In February 2018, the Govt. of India announced two major initiatives in health sector, with aim to cover preventive and health promotive interventions at primary, secondary and tertiary care system. They are as follows (69):

1. **Health and Wellness Centre:** The National Health Policy, 2017 has envisioned Health and Wellness Centers as the foundation of India's health system. Under this 1.5 lakh centers will bring health care system closer to homes of people. The health centers will provide comprehensive health care, including for non-communicable diseases and maternal and child health services. The centers will also provide free essential drugs and diagnostic services.

2. **National Health Protection Scheme:** The second flag ship programme under Ayushman Bharat is National Health Protection Scheme or Pradhan Mantri Jan Arogya Yojana (PMJAY). The details are as follows (70):

   - 71st round of National Sample Survey Organization (NSSO) has found 85.9% of rural households and 82% of urban households have no access to healthcare insurance/assurance.
   - More than 17% of Indian population spends at least 10% of household budget for health services. Catastrophic healthcare related expenditure pushes families into debt. More than 24% households in rural India and 18% population in urban area have met their healthcare expenses through some sort of borrowings.
   - Approximately 10.74 crore identified families (approximately 50 crore beneficiaries) will be entitled to get the benefits.
   - There is no cap on family size and age as well as restriction on preexisting conditions.
   - PMJAY will help reduce out of pocket hospitalization expenses, fulfill unmet needs and improve access of identified families to quality inpatient care and day care surgeries.
   - PMJAY will provide a coverage up to Rs. 5,00,000 per family per year, for secondary and tertiary care hospitalization through a network of Empaneled Health Care Providers (EHCP).
   - The EHCP network will provide completely cashless and paperless access to services for the beneficiaries at both public and private hospitals. The services will include 1350 procedures covering pre and post hospitalization, diagnostics, medicines etc.
   - PMJAY beneficiaries will be able to move across borders and access services across the country through the provider network seamlessly.
   - The scheme is entitlement based. No formal enrolment process is required.
   - PMJAY will target poor, deprived rural families and identified occupational category of urban worker's families as per the latest Socio-Economic and Caste Census (SECC) 2011 data, both rural and urban. Additionally, all such enrolled families under Rashtriya Swasthya Bima Yojana (RSBY) that do not feature in the targeted groups as per SECC data will be include as well.
   - The categories in rural and urban areas that will be covered under PMJAY are given as follows:

   For rural:
   Total deprived Households targeted for PMRSSM who
belong to one of the six deprivation criteria amongst D1, D2, D3, D4, D5 and D7:

- Only one room with kachcha walls and kachcha roof (D1)
- No adult member between age 16 to 59 (D2)
- Female headed households with no adult male member between age 16 to 59 (D3)
- Disabled member and no able-bodied adult member (D4)
- SC/ST households (D5)
- Landless households deriving major part of their income from manual casual labour (D7)

Automatically included:

- Households without shelter
- Destitute/living on alms
- Manual scavenger families
- Primitive tribal groups
- Legally released bonded labour

For Urban:

Occupational categories of workers

- Rag picker
- Beggar
- Domestic worker
- Street vendor/cobbler/hawker/other service provider working on streets
- Construction worker/plumber/mason/labour/painter/welder/security guard
- Coolie and other head-load worker
- Sweeper/sanitation worker/mali
- Home-based worker/artisan/handicrafts worker/tailor
- Transport worker/driver/conductor/helper to drivers and conductors/cart puller/rickshaw puller
- Shop worker/assistant/peon in small establishment/helper/delivery assistant/attendant/waiter
- Electrician/mechanic/assembler/repair worker
- Washer-man/chowkidar

As per the SECC 2011, the following beneficiaries are automatically excluded:

- Households having motorized 2/3/4 wheeler/fishing boat
- Households having mechanized 3/4 wheeler agricultural equipment
- Households having Kisan Credit Card with credit limit above Rs. 50,000/
- Household member is a government employee
- Households with non-agricultural enterprises registered with Government
- Any member of household earning more than Rs. 10,000/- per month
- Households paying income tax
- Households paying professional tax
- House with three or more rooms with pucca walls and roof
- Owns a refrigerator
- Owns a landline phone
- Owns more than 2.5 acres of irrigated land with 1 irrigation equipment
- Owns 5 acres of more of irrigated land for two or more crop season
- Owning at least 7.5 acres of land or more with at least one irrigation equipment.
was initiated in 1954 with the object of providing safe water and rural population of the country. In 1972 a special programme known as the Accelerated Rural Water Supply Programme was started as a supplement to the Minimum Needs Programme of the State Plans. The Central Government is supporting the efforts of the States in increased financial outlay during the successive Five Year Plans, only a small dent was made on the overall problem. During the Fifth Plan, rural water supply was included in the

The stipulated norm of water supply is 40 litres of safe water per capita per day, and at least one hand pump/spot-source for every 250 persons. Information, education and communication is an integral part of rural sanitation programme to adopt proper environmental sanitation practices including disposal of garbage, refuse and waste water, and to convert all existing dry latrines into low cost sanitary latrines. The priority is to evolve financially viable sewerage systems in big cities and important pilgrimage and tourist centres and recycling of treated effluents for horticulture, irrigation and other non-domestic purposes.

The programme was revised from Ist April 2009 and named as National Rural Drinking Water Programme (60). It is now a component of Bharat Nirman which focuses on the creation of rural infrastructure.

**Bharat Nirman**

Bharat Nirman was launched by the Government of India in 2005 as a programme to build rural infrastructure. While phase-I was implemented in the period of 2005-06 to 2008-09, the phase-II was implemented from 2009-10 to 2011-12. At the beginning of phase-I period, priority was given to cover water quality problem and other contaminants, e.g., arsenic and fluoride affected habitations followed by iron, salinity, nitrate.

**New initiatives in 12th Five Year Plan**

1. In order to raise coverage of piped water supply, toilet coverage and strengthening of institutions and systems in rural drinking water and rural sanitation sectors the Ministry has proposed a Rural Water Supply and Sanitation Project for low income states;

2. Enhancement of service levels for rural water supply from the norm of 40 lpcd to 55 lpcd for designing of system. The target being at least 50 per cent of rural population in the country to have access to water within their household premises or within 100 metres radius, with at least 30 per cent having individual household connections, as against 13 per cent today (74).

**Swachh Bharat Mission (74)**

Swachh Bharat Abhiyan or Swachh Bharat Mission is a national campaign by the government of India to clean streets, roads and infrastructure of the country. The campaign was officially launched by Prime Minister of India on 2nd Oct, 2014, at Rajghat, New Delhi. It aims to eradicate open defecation by year 2019, by constructing 12 million toilets in rural India. Mission has two sub-missions, namely, Swachh Bharat Mission Urban, and Swachh Bharat Mission Gramin.
**Swachh Bharat Mission Gramin (SBM-G) (75)**

The Mission in rural India will mean improving the level of cleanliness in rural areas through solid and liquid waste management and making gram panchayats free of open defecation, clean and sanitized. The programme includes the key components of earlier sanitation schemes.

The key objectives of the programme are as follows:

(a) Bring about an improvement in the general quality of life in the rural areas, by promoting cleanliness, hygiene and eliminating open defecation;
(b) Accelerate sanitation coverage in rural area to achieve the vision of Swachh Bharat by 2nd October 2019;
(c) Motivate Communities and Panchayati Raj Institutions to adopt sustainable sanitation practices and facilities through awareness creation and health education;
(d) Encourage cost effective and appropriate technologies for ecologically safe and sustainable sanitation; and
(e) Develop wherever required, community managed sanitation systems focusing on scientific solid & liquid waste management systems for overall cleanliness in the rural areas.

The key components of SBM-G include, start up activities including preparation of state plan; construction of household toilets; construction of community sanitary complexes; and capacity building of functionaries etc. Under the programme, construction of toilets in government schools and anganwadi centres will be done by the Ministry of Human Resource Development and Ministry of Women and Child Development respectively. Rural School sanitation intervention which shall be implemented under the programmes of the Department of School Education.

A duly completed household sanitary toilet shall comprise of toilet unit including a substructure which is sanitary (that safely confines human faeces and eliminates the need of human handling before it is fully decomposed), a superstructure, with water facility and hand wash unit for cleaning and hand washing. The Mission aims that all rural families have access to toilets. Incentives for construction of household toilets will be available for below poverty line households, and above poverty line households restricted to SCs/STs, small and marginal farmers, landless labourers, physically handicapped and women headed families.

**Swachh Bharat Mission–Urban (SBM-U) (76)**

Swachh Bharat Mission–Urban (SBM-U) is being implemented by Ministry of Urban Development. The main objectives of the mission are as follows:

1. Elimination of open defecation;
2. Eradication of manual scavenging;
3. Modern and scientific municipal solid waste management;
4. To effect behavioural change regarding healthy sanitation practices;
5. Generate awareness about sanitation and its linkage with public health;
6. Capacity augmentation for ULB’s; and
7. To create an enabling environment for private sector participation in Capex (capital expenditure) and Opex (operation and maintenance).

**Mission components**

The Mission has the following components:

1. Household toilets, including conversion of insanitary latrines into pour-flush latrines;
2. Community toilets;
3. Public toilets;
4. Solid waste management;
5. IEC & public awareness; and
6. Capacity building and administrative & office expenses.

By Public Toilets, it is implied that these are to be provided for the floating population/public in places such as markets, train station, tourist places, near office complexes, or other public areas where there are considerable number of people passing by.

By Community Toilets, it is implied that a shared facility provided by and for a group of residents or an entire settlement. Community toilet blocks are used primarily in low-income and/or informal settlements / slums, where space and/or land are constraints in providing a household toilet. These are for a more or less fixed user group.

All statutory towns will be covered under the mission. The special focus group under the mission are as follows:

I. All manual scavengers in urban areas are identified, insanitary toilets linked to their employment are upgraded to sanitary toilets, and the manual scavengers are adequately rehabilitated.

II. In their efforts to streamline and formalize SWM systems it shall be the endeavor of ULBs that the informal sector workers in waste management (rag pickers) are given priority to upgrade their work conditions and are enumerated and integrated into the formal system of SWM in cities;

III. All temporary accommodation for migrants and the homeless in urban areas have adequate provision for toilets either on the premises or linked to a public/community toilet;

IV. Mandating that construction labour in urban areas have access to temporary toilets at all sites in urban areas, buildings, parks and roads where construction / maintenance work is taking place or where construction labour is temporarily housed; and

V. Priority shall be accorded pro-actively to cover households with vulnerable sections such as pensioners, girl children, pregnant and lactating mothers.

**Household toilet component of SBM-Urban**

SBM (Urban) aims to ensure that —

(a) No households engage in the practice of open defecation;
(b) No new insanitary toilets are constructed during the mission period; and
(c) Pit latrines are converted to sanitary latrines

The target group for construction of household units of toilets, thus, is:

(i) 80% of urban households engaging in open defecation;
(ii) All households with insanitary latrines; and
(iii) All households with single-pit latrines.

These will be targeted under this component for the construction of household toilets or individual household latrines during the mission period. The remaining 20% of
households practicing open defecation will be catered by community toilets, due to constraints of space.

Household toilets constructed under SBM (Urban) will have two main structures – the toilet superstructure (including the pan and water closet), and the sub-structure, either an on-site treatment system or a connection to existing underground sewerage system.

Solid waste management component of SBM–Urban

Municipal Solid Waste Management (MSWM) refers to a systematic process that comprises of waste segregation and storage at source, primary collection, secondary storage, transportation, secondary segregation, resource recovery, processing, treatment, and final disposal of solid waste.

MINIMUM NEEDS PROGRAMME

The Minimum Needs Programme (MNP) was introduced in the first year of the Fifth Five Year Plan (1974–78). The objective of the programme is to provide certain basic minimum needs and thereby improve the living standards of the people. It is the expression of the commitment of the government for the "social and economic development of the community particularly the underprivileged and underserved population". The programme includes the following components:

- Rural Health
- Rural Water Supply
- Rural Electrification
- Elementary Education
- Adult Education
- Nutrition
- Environmental improvement of Urban Slums
- Houses for landless labourers

There are two basic principles which are to be observed in the implementation of MNP: 
(a) the facilities under MNP are to be first provided to those areas which are at present underserved so as to remove disparities between different areas; 
(b) the facilities under MNP should be provided as a package to an area through Intersectoral Area Projects, to have a greater impact.

In the field of rural health, the objectives to be achieved by the end of the Eight Five Year Plan, under the minimum needs programme were: one PHC for 30,000 population in plains and 20,000 population in tribal and hilly areas; one sub-centre for a population of 5,000 people in the plains and for 3000 in tribal and hilly areas, and one community health centre (rural hospital) for a population of one lakh or one C.D. Block by the year 2000. The establishment of PHCs, sub-centres, upgrading of PHCs, and construction of buildings thereof are all included in the State sector of the minimum needs programme.

In the field of nutrition, the objectives are: 
(a) to extend nutrition support to 11 million eligible persons; 
(b) to expand "special nutrition programme" to all the ICDS projects; and 
(c) to consolidate the mid-day meal programme and link it to health, potable water and sanitation.

20-POINT PROGRAMME

In addition to the Five Year Plans and Programmes, in 1975, the Govt. of India initiated a special activity. This was the 20-Point programme - described as an agenda for national action to promote social justice and economic growth.

On August 20, 1986, and again in 2006, the existing 20-Point Programme was restructured. Its objectives are spelt out by the Government as "eradication of poverty, raising productivity, reducing inequalities, removing social and economic disparities and improving the quality of life".

The 20 points of twenty point programme 2006 are as follows (77):

1. Poverty eradication
2. Power to people
3. Support to farmers
4. Labour welfare
5. Food security
6. Housing for all
7. Clean drinking water

In September 2000, the UN General Assembly adopted the Millennium Declaration, establishing a global partnership of countries and development partners committed to eight voluntary development goals, to be achieved by 2015. Representing ambitious moral and practical commitments, the MDGs called for action to: (1) eradicate extreme poverty and hunger; (2) achieve universal primary education; (3) promote gender equality and empower women; (4) reduce child mortality; (5) improve maternal health; (6) combat HIV/AIDS, malaria and other diseases; (7) ensure environmental sustainability; and (8) develop a global partnership for development. Three of the eight MDGs are focused on health, while health is also a component of several other MDGs (nutrition, water and sanitation) (1).

The MDGs have been more influential than any other attempt at international target setting in the field of development. The rapid acceleration of global progress towards the poverty reduction, gender, health and education goals since 2000, and particularly since 2005, is just one example of their beneficial impact. The adoption of a simple, clear and time-bound framework that is compelling, easy to communicate and measurable has been one of the MDGs' great strengths, encouraging donor governments, international agencies and country decision-makers to focus attention on areas of need, and to measure the results of initiatives taken. And while it is hard to isolate specific casual effects, it seems reasonable to suppose that the intensity of focus (and investment) has been a key driver of the rapid acceleration of global progress towards the poverty reduction, gender, health and education goals since 2000, and particularly since 2005.

Health in the MDG: achievements

Progress towards the MDGs has, on the whole, been remarkable. With regard to extreme poverty, for example, the number of people living on less than US$ 1.25 per day has declined by more than half, from 1.9 billion in 1990 to 836 million in 2015. Similarly, the proportion of undernourished people in the developing regions has fallen from 23% in 1990-1992 to 13% in 2014-2016. The child undernutrition indicator target has almost been met (1). Deaths among pregnant women, children and adolescents account for more than one third of the global burden of premature mortality, despite the fact that the vast majority of these deaths are preventable. Rates of maternal mortality are 19 times higher in developing countries than in developed countries and children in developing countries are 8 times more likely to die before they reach five years of age (1). Despite substantial progress on maternal and child mortality neither MDG 4 nor MDG 5 targets were met. The global under five mortality rate reduced by 53 per cent between 1990 and 2015. Short of the targeted two thirds reduction and the global maternal mortality ratio declined by 44 per cent, well short of the targeted 75 per cent fall. The least developing countries continue to face the greatest challenges in improving maternal and child health, struggling with a combination of poor coverage and quality of health care services and public health interventions, inadequate water and sanitation, poor infrastructure, low food security and limited education and economic opportunity. These same countries also face obstacles in ensuring universal access to sexual and reproductive health services, as well as guarding the health of adolescents, the challenges that are shared by most world regions (1).

Maternal mortality is the second leading cause of death among women aged 15-49 years, after HIV. Globally women face a 1 in 180 lifetime risk of dying due to maternal causes, which are dominated by haemorrhage, hypertensive disorder, sepsis and abortion. In African region, however, the MMR is still running at 540 per 100,000 live births, which combined with the high level of fertility, translates into life-time risk of dying from maternal causes at 1 in 37 (1).

The target of achieving universal access to reproductive health (MDG 5.B) was only added to MDG 5 in the year 2007, but some progress has been made. MDG 5.B included four specific indicators: adolescent birth rate; antenatal care visits; contraceptive prevalence rate; and unmet need for family planning. Improvement in these areas are expected to reduce maternal mortality since high fertility rates are correlated with an increased life-time risk of dying from maternal causes. Based on the current projections, the adolescent birth rate reduced from 59 births per 1000 women age 15-49 years in 1990 to 51 per 1000 women in 2015. Decline in the adolescent birth rate was greater in developed countries (50 per cent) than in developing countries (13 per cent). However, Southern Asia had an impressive 47 per cent decline. With regard to recommended four or more antenatal visits, coverage in developing regions nearly doubled, increasing from 31 per cent in 1990 to 60 per cent in 2013. Skilled birth attendance coverage also increased in East Asia, Pacific and Latin America. About 9 in 10 births now occur in health facilities.
In contrast South Asia and sub-Saharan Africa; where the burden of maternal and newborn deaths is highest, only about 45 per cent and 46 per cent respectively are delivered in health facilities (1).

Despite population growth in developing regions, the number of deaths of children under 5 has declined from 12.7 million in 1990 to almost 6 million in 2015 globally. The measles vaccination helped to prevent nearly 15.6 million deaths between 2000 and 2013. The number of reported measles cases also declined by 67 per cent for the same period. The major causes of newborn mortality in 2015 are prematurity, birth related complications and neonatal sepsis while leading causes of child death in post neonatal period are pneumonia, diarrhoea, injuries and malaria, which calls for efforts to ensure that all children have access to early childhood developmental care. Pre-primary education is likely to have an impact on child mortality, while improving child’s chances of living.

As regards to Goal 6 – new HIV infection has reduced by approximately 40 per cent between 2000 and 2014, from an estimated 3.5 million cases to 2.1 million by 2014, 14.9 million people living with HIV were receiving ART globally, an immense increase from just 800,000 in 2003, ART averted 7.5 million deaths from AIDS between 1995 and 2003.

Over 6.2 million malaria deaths have been averted between 2000 and 2015, primarily of children under 5 years of age in sub-Saharan Africa. The global malaria incidence rate has fallen by an estimated 37 per cent and the mortality rate by 58 per cent. More than 58 per cent children under 5 years of age in sub-Saharan Africa were sleeping under ITN in 2015 as compared to 2 per cent in 2000 (1).

TB case detection rate increased from 38 per cent to 68 per cent, while maintaining high levels of treatment success (85 per cent or higher) since 2007 (1, 2).

The spread of infectious diseases is affected by multiple socio-economic, environmental, and ecological factors as well as rapidly increasing antimicrobial resistance. Infectious disease outbreak remains a concern to all countries, imposing a significant burden on economies and public health. Several respiratory infectious disease outbreaks have occurred since 2000, including the 2003 SARS epidemic and 2009 A (H1N1) influenza virus pandemic. Cholera is endemic in many countries. Most recently the outbreak of Ebola virus disease in West Africa resulted in over 28000 cases and more than 11295 deaths (as of 23rd September 2015) causing considerable concern across the globe.

As regards Goal 7 – The world has now met the target relating to access to safe drinking water. In 2012, 90 per cent of the population used an improved source of drinking water compared to 76 per cent in 1990. However, progress has been uneven across different regions, between urban and rural areas and between rich and poor. With regard to basic sanitation, current rate of progress is too slow for the MDG target to be met globally. In 2012, 2.5 billion people did not have access to improved sanitation facility with 1 billion of these people still practicing open defecation. The number of people living in urban areas without access to improved sanitation is increasing because of rapid growth in the size of urban population (3).

It is generally agreed that the MDGs have been a success. They have been more influential and achieved wider public recognition than any other attempt of international target setting in the field of development. However, there remain several targets where progress has been limited and there remains unfinished agenda to complete work on the health MDGs. These unfinished agenda is reflected in the Sustainable Development Goals (1).

Table 1 shows the detailed information regarding the indicators of health related MDGs in India, i.e. the baseline (1990) and current level data.

new era as on Ist January 2016, the SDGs of the 2030 (MDGs) came to the end of their term, and a post-2015 Agenda, comprising of 17 Sustainable Development Goals Agenda for Sustainable Development officially came into force. While progress towards the MDGs has been impressive in many ways, much work remains to be done. In

Determination, an adequate standard of living, food, water and sanitation, good governance and the rule of law), it does not specifically mention that health is a human right (1). They recognize that ending poverty must go hand-in-hand with strategies that build economic growth and addresses a range of social needs including education, health, social protection, raising basic standard of living, job opportunities, while tackling climate changes and environmental protection. The five Ps of the new agenda are people, planet, prosperity, peace and partnership.

The sustainable development has been defined as “development that meets the needs of the present without compromising the ability of future generations to meet their own needs” (4). Implementation of SDGs and the success will rely on countries sustainable development policies, plans and programmes. It will require resource mobilization and financing strategies. All stakeholders : governments, civil societies, the private sector, and others are expected to contribute to the realization of the new agenda.

The 2030 Agenda is designed to benefit all. Universal in scope, the agenda will require a comprehensive, integrated approach to sustain development, as well as collective action at all levels. “Leaving no one behind” will be an overarching theme. The paragraph 26 of the 2030 agenda addresses health as follows :

“The promotion of physical and mental health and well-being, and to extend life expectancy for all, we must achieve universal health coverage and access to quality health care. No one must be left behind. We commit to accelerating the progress made to date in reducing newborn, child and maternal mortality by ending all such preventable deaths before 2030. We are committed to ensuring universal access to sexual and reproductive health-care services, including for family planning, information and education. We will equally accelerate the pace of progress made in fighting malaria, HIV/AIDS, tuberculosis, hepatitis, Ebola and other communicable diseases and epidemics, including by addressing growing anti-microbial resistance and the problem of unattended diseases affecting developing countries. We are committed to the prevention and treatment of non-communicable diseases, including behavioural, developmental and neurological disorders, which constitute a major challenge for sustainable development” (1).

Health is centrally positioned within the 2030 Agenda, with one comprehensive goal - SDG 3 : Ensure healthy lives and promote well-being for all ages. Goal 3 includes 13 targets covering all major health priorities with four targets on the unfinished and expended millennium development goals, four targets to address non-communicable diseases, mental health, injuries and environmental issues and four “means-of-implementation” targets. The Universal Health Coverage (UHC) is the key to achievement of all targets and development of strong resilient health system. The SDGs are not solely focused on developing countries. Thus, while some targets and indicators may be more relevant for developing countries, SDG monitoring should in principle cover all.

Even though the 2030 Agenda refers several times to the term “human right(s)” (right to development, self determination, an adequate standard of living, food, water and sanitation, good governance and the rule of law), it does not specifically mention that health is a human right (1).

Table 2 enumerates the 13 targets of goal 3 with their proposed indicators. It shows that millennium development goals on maternal mortality (3.1) child mortality (3.2) and infectious diseases (3.3) have been retained in SDG

**Goal 7 : Ensure environmental sustainability**

**Goal 8 : Develop global partnership for development**

**Goal 17 : In cooperation with pharmaceutical companies, provide access to affordable, essential drugs in developing countries**

**Goal (G), Target (T), Indicator (I), (Goals 2 & 3 are not pertaining to health)**

**SUSTAINABLE DEVELOPMENT GOALS**

In December 2015, the Millennium Development Goals (MDGs) came to the end of their term, and a post-2015 Agenda, comprising of 17 Sustainable Development Goals (SDGs) takes their place. World stands at the threshold of a new era as on 1st January 2016, the SDGs of the 2030 Agenda for Sustainable Development officially came into force. While progress towards the MDGs has been impressive in many ways, much work remains to be done. In health, unprecedented progress has been made in reducing maternal and child mortality and in the fight against infectious diseases; even though several global and country MDG targets are not met. The dramatic progress of MDGs paves the way for more ambitious achievements by 2030. Notable among them are the challenges of acute epidemic diseases, disasters, conflict situations, the newly spreading epidemic of noncommunicable diseases, mental health disorders, and large inequalities in all parts of the world. The new goals are unique in that they call for action by all countries to promote prosperity while protecting the planet.

<tbody>
<tr>
<td>3.1 (a) By 2030, reduce the global maternal mortality ratio to less than 70 per 100,000 live births.</td>
<td>3.1.1 Maternal deaths per 100,000 live births. Global—216, India—130 (2014–16)</td>
</tr>
<tr>
<td>3.1 (b) By 2030, end preventable deaths of newborns and children under 5 years of age, with all countries aiming to reduce neonatal mortality to at least as low as 12 per 1,000 live births and under-5 mortality to at least as low as 25 per 1,000 live births.</td>
<td>3.1.2 Proportion of births attended by skilled health personnel. Global—73, India—81.4 (2007–17)</td>
</tr>
<tr>
<td>3.1 (c) By 2030, end the epidemics of AIDS, tuberculosis, malaria and neglected tropical diseases and combat hepatitis, water-borne diseases and other communicable diseases.</td>
<td>3.1.3 Under-5 mortality rate (deaths per 1,000 live births). Global—48.9, India—47.7 (2016). 3.1.4 Neonatal mortality rate (deaths per 1,000 live births). Global—18.6, India—25.4 (2016). 3.1.5 Number of new HIV infections per 100,000 uninfected population (by age group, sex and key populations). Global—0.25%, India—0.16% (2016). 3.1.6 Tuberculosis incidence per 1,000 persons per year. Global—140, India—211 (2016). 3.1.7 Malaria incident cases per 1,000 persons per year. Global—88, India—18.8 (2016). 3.1.8 Number of new hepatitis B infections per 100,000 population in a given year. The multidrug resistant strain is included. 3.1.9 Malaria incidence per 1,000 persons per year. Global—11.7, India—18.7 (2016). 3.1.10 Number of people requiring interventions against neglected tropical diseases. Global—149.7,35 million, India—458,855 million (2016). 3.1.11 Mortality of cardiovascular disease, cancer, diabetes or chronic respiratory disease. Global—16–16.3 (2016).</td>
</tr>
<tr>
<td>3.1 (d) Strengthen the implementation of the World Health Organization Framework Convention on Tobacco Control in all countries, as appropriate.</td>
<td>3.1.12 Coverage of treatment interventions: pharmaceutical, psychosocial and rehabilitation and tobacco-free services for substance use disorders. Global—64, India—57 (2016).</td>
</tr>
<tr>
<td>3.1 (e) Strengthen the prevention and treatment of substance abuse, including narcotic drug abuse and harmful use of alcohol.</td>
<td>3.1.13 Harmful use of alcohol, defined according to the national context as alcohol per capita consumption (aged 15 years and older) within a calendar year in litres of pure ethanol. Global—6.4, India—5.7 (2016). 3.1.14 Number of road traffic fatal injuries within 30 days per 100,000 population (age-standardized). Global—18.4, India—16.6 (2013). 3.1.15 Percentage of women of reproductive age (aged 15–49) who have their need for family planning satisfied with modern methods. Global—72%, India—73% (2016). 3.1.16 Adolescent birth rate (per 1,000 girls aged 15–19) per 100,000 women in that age group. Global—54.9, India—28.1 (2007–17).</td>
</tr>
<tr>
<td>3.2 (a) By 2030, ensure universal access to sexual and reproductive health-care services, including for family planning, information, education, and the integration of reproductive health into national strategies and programmes.</td>
<td>3.2.1 Percentage of female and male (aged 15–49) who are satisfied with modern methods for contraceptive use. Global—69%, India—61% (2016). 3.2.2 Number of new HIV infections per 100,000 uninfected population in a given year. The multidrug resistant strain is included. 3.2.3 Malaria incident cases per 1,000 persons per year. Global—82, India—70 (2014). 3.2.4 Mortality of cardiovascular disease, cancer, diabetes or chronic respiratory disease. Global—15–16.3 (2016). 3.2.5 Number of people requiring interventions against neglected tropical diseases. Global—82, India—70 (2014).</td>
</tr>
<tr>
<td>3.2 (b) Achieve universal health coverage, including financial risk protection, access to quality essential health-care services and access to safe, effective, quality and affordable essential medicines and vaccines for all.</td>
<td>3.2.6 Coverage of trachoma interventions (e.g., child full immunization, antiretroviral therapy, tuberculosis treatment, hypertension treatment, skilled attendant at birth, etc.) for the population affected by trachoma. Global—43, India—28 (2007–17). 3.2.7 Mortality of cardiovascular disease, cancer, diabetes or chronic respiratory disease. Global—15–16.3 (2016). 3.2.8 Number of new HIV infections per 100,000 uninfected population in a given year. The multidrug resistant strain is included. 3.2.9 Malaria incident cases per 1,000 persons per year. Global—82, India—70 (2014). 3.2.10 Mortality rate attributed to hazardous drinking per 1,000 population (ages 15–49) in litres of pure ethanol. Global—11.7, India—18.7 (2016). 3.2.11 Age-standardized prevalence of smoking among persons aged 15–49 years. Global—20.6, India—19 (2016). 3.2.12 Number of new HIV infections per 100,000 uninfected population in a given year. The multidrug resistant strain is included. 3.2.13 Malaria incident cases per 1,000 persons per year. Global—82, India—70 (2014).</td>
</tr>
<tr>
<td>3.3 (a) By 2030, substantially reduce the number of deaths and injuries from road traffic accidents.</td>
<td>3.3.1 Health worker density and distribution per 10,000 population. Global—25, India—30.2 (2006–13). 3.3.2 Maternal deaths per 100,000 live births. Global—216, India—130 (2014–16). 3.3.3 Number of new HIV infections per 100,000 uninfected population in a given year. The multidrug resistant strain is included. 3.3.4 Malaria incident cases per 1,000 persons per year. Global—82, India—70 (2014). 3.3.5 Mortality of cardiovascular disease, cancer, diabetes or chronic respiratory disease. Global—15–16.3 (2016). 3.3.6 Number of people requiring interventions against neglected tropical diseases. Global—82, India—70 (2014). 3.3.7 Number of new HIV infections per 100,000 uninfected population in a given year. The multidrug resistant strain is included. 3.3.8 Malaria incident cases per 1,000 persons per year. Global—82, India—70 (2014).</td>

framework and expanded to include neonatal mortality and more infectious diseases such as hepatitis and waterborne diseases. The target on access to sexual and reproductive health care services (3.7) and access to vaccines and medicines (3.8) are also closely related to MDG targets. Sexual and reproductive rights are addressed under MDG 5 on gender equality. The SDGs include new targets on non-communicable diseases and mental health (3.4), substance abuse (3.5), injuries (3.6), health impact from hazardous chemicals, water and soil pollution and contamination (3.9), and the implementation of the WHO framework convention on tobacco control (3.1). Target 3.d addresses reducing and the implementation of the WHO framework convention on tobacco control (3.1). Target 3.d addresses reducing and the implementation of the WHO framework convention on tobacco control (3.1). Target 3.d addresses reducing and the implementation of the WHO framework convention on tobacco control (3.1). Target 3.d addresses reducing and the implementation of the WHO framework convention on tobacco control (3.1).

Universal health care (UHC) is also a new target (3.8), which provides an overall framework for the implementation of a broad and ambitious agenda in all countries. UHC is the only target that cuts across all targets of health goal, as well as linked to health-related targets in other goals (1).

Health is linked to many of the non-health goals, reflecting the fact that health affects and in turn is affected by many economic, social and environmental determinants. More than a dozen targets in other goals can be considered health-related and should be given special attention in strategies, policies and plans to achieve the health goal and in monitoring progress. Table 3 shows the targets in other goals linked to health SDG 3.

At the global level the SDGs will be monitored and reviewed using a set of global indicators developed by the Inter Agency and Expert Group on SDG Indicators. The governments will also develop their own national indicators to assist in monitoring progress made on the goals and targets.

Almost all targets of goal 3 can be linked to strategies and global action plans that have been adopted by World Health Assembly in recent years or are under development. However, there are few gaps, e.g., there is no mention of immunization coverage as a specific target although it is integral to the achievement of at least four targets that are listed. Access to sexual and reproductive health care is included, but sexual and reproductive rights, violence and discrimination against women and girls are dealt with elsewhere (goal 5), older people are mentioned in goal 2. The aging population as an important implication for health system is absent except indirectly through its impact on non-communicable diseases and mental health.

Fig. 1 presents these targets in a way that distinguishes those that have been carried forward and enhanced from the MDGs, those that have been added and those that are means of implementations.

**Reproductive, maternal, newborn and child health**

Multiple targets in SDG 3 and other goals refer to reproductive, maternal, newborn and child health (RMNCH). These include targets for mortality, service coverage, risk factors and health determinants (Table 4). The global strategy for Women's, Children's and Adolescent's Health, 2016-2030 is fully aligned with the SDG target and is organized around the broad themes of “Survive-Thrive-Transform”. It is an example of how a range of health and health-related goals and targets must be addressed to improve health and well-being of women, children and adolescents.

New in the SDGs is the emphasis on youth as a vulnerable population. Though, generally a healthy group, adolescents are exposed to a range of risks and diseases. As many health behaviours established during adolescence have profound effect over rest of the life course, they are a population deserving more concerted attention. Globally, road injuries, HIV/AIDS and self-harm are the leading causes of adolescent death.

Reproductive, maternal, newborn and child health is one of the four categories of the universal health coverage indicators: family planning, antenatal care (four visits or more) with skilled attendance at birth; full child immunization coverage and health-seeking behaviour for suspected child pneumonia. The indicator for SDG target 2.2 on ending all forms of malnutrition are focused on stunting, wasting and overweight among children under 5 years of age. Children are at greater risk of stunting if they are born in rural areas, poor household or to mothers...
denied basic education. Several environmental targets and indicators are also relevant to this group. They include water and sanitation, and air pollution (causes for diarrhoea and pneumonia in under 5 age group).

Infectious diseases

The main target relating to infectious diseases is SDG 3.3, which refers to ending the epidemic of AIDS, tuberculosis, malaria and neglected tropical diseases, and combating hepatitis, water-borne diseases and other communicable diseases. Table 5 shows the selected targets and proposed indicators linked to infectious diseases by type of indicator.

The SDG targets for infectious diseases are very ambitious, but are in line with what a number of disease-specific strategies and World Health Assembly resolutions have already been exploring. For all infectious diseases, the targeted reductions aimed at progressing towards elimination goals in the coming 15 years far outstrip what has been achieved since 2000.

New strategies include (1):
- UNAIDS global strategy fast track: Ending the AIDS epidemic by 2030 and the draft WHO Global Health Sector Strategy on HIV 2016–2021;
- The End TB strategy;
- Global technical strategy for Malaria 2016–2030;
- NTD roadmap, and water sanitation and hygiene for accelerating and sustaining progress on NTDs: A global strategy 2015–2020; and

Source: (1)

The battle against infectious diseases need to focus on the preventive efforts complemented by rapid diagnosis and effective treatment. A number of common strategic priorities can be identified for all infectious diseases. Importance of new drugs and vaccines to combat infectious diseases; behavioural changes such as safe sex and condom use to reduce HIV, STD and hepatitis B transmission; harm reduction for people who inject drugs to prevent HIV, HBV and HCV acquisition; use of insecticide treated nets for malaria prevention; and improved health-care safety to reduce nosocomial transmission of HIV, hepatitis and other pathogens. Preventive chemotherapy based on large-scale delivery of free, safe, single-dose, quality-assured medicines at regular intervals is a cornerstone of tackling neglected tropical diseases. Child vaccination is a priority intervention to combat hepatitis B, and rotavirus vaccination to reduce the incidence of diarrhoea. For other diseases, continued investment in the development of vaccines are needed which may pay off in the coming 15 years.

Noncommunicable diseases and mental health

As shown in Table 7, unlike the MDGs, the SDGs include a specific target for noncommunicable diseases (NCDs) and several NCD-related targets. Target 3.4 calls for a one third reduction in premature mortality from NCDs by 2030, and is an extension of the global voluntary NCD mortality target. It defines premature NCD mortality as the probability of dying from any of the main NCDs between the age 30 and 70 years. Other targets include: Target 3.3 on improvements in tobacco control; target 3.5 on substance abuse, including harmful use of alcohol along with mental health; target 3.6...
on supporting research and development of vaccines and medicines for NCDs that primarily affect developing countries, as well as providing access to affordable essential medicines and vaccines for NCDs; and target 3.9 on deaths and illnesses related to hazardous chemicals, as well as air, water and soil pollution and contamination. Finally 3.8 target addresses universal health care which has implication for a wide range of NCD- related promotion, prevention and treatment interventions (4).

Source: (4)

Lack of awareness and late detection is an issue with all leading NCDs and it is essential to support and develop primary health-care services required for their early detection and management. An integrated approach to NCD care is more effective, e.g., the monitoring of blood pressure status should be integrated with monitoring of blood cholesterol and blood sugar. The prevention of heart attacks and strokes through a “total cardiovascular risk approach” is more cost-effective than treatment based on individual risk factor thresholds only, and should be part of the basic package of UHC.

The SDG targets for NCDs is based on previous UN and WHO declarations that provide strategic directions. In the year 2014 the UN General Assembly adopted Outcome Document on NCDs with national targets for 2025. Of these targets first target is closely linked to SDG target 3.4. The Global Voluntary Indicators are as follows (1):

1. A 25% relative reduction in the risk of premature mortality from CVD, cancer, diabetes or CRD;
2. At least 10% relative reduction in the harmful use of alcohol;
3. A 10% relative reduction in prevalence of insufficient physical activity;
4. A 30% relative reduction in mean population intake of salt/sodium;
5. A 30% relative reduction in prevalence of current tobacco use;
6. A 25% relative reduction in the prevalence of raised blood pressure;
7. Halt the rise in diabetes and obesity;
8. At least 50% of eligible people receive drug therapy and counselling (including glycaemic control) to prevent heart attacks and strokes; and
9. An 80% availability of the affordable basic technologies and essential medicines, including generics, required to treat major NCDs in both public and private facilities.

Mental disorder occurs in all regions and cultures of the world. The most prevalent being depression and anxiety, which are estimated to affect nearly one in 10 people. At its worst, depression can lead to suicide. Globally, among young adults aged 15–29 years, suicide accounts for 8.5 per cent of all deaths and is second leading cause of death in this group after road traffic injuries (4).

Substance use and substance-use-disorder including the harmful use of alcohol cause a significant public health burden. Worldwide alcohol consumption in 2015 was estimated to be 6.3 litres of pure alcohol per person aged 15 years or older. Tobacco use is a leading risk factor for NCDs and SDG 3.a addresses the implementation of the WHO Framework Convention on Tobacco Control; with tobacco use selected as an indicator of progress. In 2015, over 1.1 billion people used tobacco (4).

Air pollution is a major risk factor for NCDs causing cardiovascular diseases, stroke, chronic obstructive pulmonary disease and lung cancer as well as increasing the risk of acute respiratory infections. In 2012, ambient air pollution (from traffic, industrial sources, waste burning or residential fuel combustion) caused 3 million deaths. Target 11.6 focuses on urban environmental health and includes an indicator on the annual mean level of the particulate matter such as PM 2.5 and PM10 in cities.

### Injuries and violence

Unlike the MDGs, injuries and violence are included in multiple SDGs targets. Road traffic injuries and unintentional injuries are included in the health goal with targets related to violence and disasters as part of other goals as shown in Table 8.

### TABLE 8

Source: (4)

Injuries sustained accidentally or as a result of intentional act of violence, kill more than 5 million people worldwide annually. It accounts for 9 per cent of global mortality. The leading cause of injury deaths is road traffic injury, followed by suicide, fall and interpersonal violence. Other important cause of injuries include drowning, fires and burns, poisoning, war and conflict and natural disasters.
Each year about 1.25 million people die from road traffic injuries and another 20–50 million people sustain non-fatal injuries as a result of road traffic collisions or crashes. Road traffic injuries are among the top 10 causes of deaths globally and the leading cause of death for people in 15–29 years age group. Homicide and collective violence accounts for around 10 percent of global injury related death. Four-fifths of homicide victims are men and 60 percent of victims are of 15–44 years age group (1).

A proposed indicator for SDG target 16.1 is conflict death per lac population. In 2015, it is provisionally estimated that 152,000 people were killed in wars and conflicts, corresponding to about 0.3 per cent of global deaths (4).

### Health system

Health system strengthening is a core focus of the SDGs. This is reflected by the fact that universal health care (UHC) is central to the overall health goal as set out in SDG declaration and is assigned a special target (3). In order to move towards the UHC goal, country health system needs to be strengthened as well as adapted to meet the shifting health priorities associated with demographic and epidemiological transition, rapidly developing technologies and changing public expectations. Table 9 shows the targets and indicators linked to health system.

Source: (4)

Access to affordable medicines and vaccines on a sustainable basis is an indicator to SDG target 3.b which focuses on support for research and development and on the affordability of medicines and vaccines for communicable diseases and non-communicable diseases that primarily affect developing countries. A second indicator under SDG target 3.b aims to capture the level of research and development investments.

The transition from MDGs to SDGs cannot be seen solely as exchange of a short list of goals and targets for a longer one. The SDGs are fundamentally different to the MDGs, as is the political context in which they have been developed, and as in which they will be implemented. The MDGs had a consistent and more or less singular purpose. They were about the achievement of improved human development outcome (primarily in terms of poverty, education and health) in developing countries. They were closely associated with aid spending. The SDGs in the words of declaration are “integrated and indivisible, global in nature and universally applicable”. It is relevant to all countries and not just about developing countries.

While MDGs were about limited set of human development targets, the SDGs cover the economic, environmental and social pillars of sustainable development with strong focus on equity; expressed more frequently in the phrase “no one will be left behind”.

Several health targets follow on from the unfinished MDG agenda and many are derived from World Health Assembly resolutions and related Action Plans (1).

### India and Sustainable Development Goals (6)

As the MDGs reached their December 2015 deadline, the new set of Sustainable Development Goals were being adapted by India also. There is now a remarkable convergence of vision underlying the priorities for the proposed SDGs and those of the new government in India. Building on the MDGs, the SDGs propose to end poverty and deprivation in all forms, leaving no one behind, while making development economically, socially and environmentally sustainable. The government of India has also adopted the principle of Sabka Sath Sabka Vikas ("together with all, development for all"), with pledge that the first claim on development belong to the poor. The government is calling for improved sanitation, health education, financial inclusion, security and dignity for all, especially women. The priority is improving environmental development with respect to water, air, soil and biosphere by treating challenges of climate change adaptation as an opportunity rather than a problem.

India can progress towards sustainable development in health if health is high on the national and state agenda. This requires high political commitment. India should invest in public health and finish agenda through further improvement in maternal and child health, confronting neglected tropical diseases, eliminating malaria, AIDS and hepatitis and increasing the light against TB. For all these challenges, the programmes and interventions need to give quality services, with implementation of universal health care. India needs to built robust health system in all aspects and strengthen both the urban and rural components, with primary health care at its centre. More involvement of private health sector is vital. India needs to develop a strong system for monitoring, evaluation and accountability.

The goal of sustainable development cannot be achieved globally without India, and the world will be watching how India will implement its new strategic directives.

Demography, as understood today, is the scientific study of human population. It focuses its attention on three readily observable human phenomena: (a) changes in population size (growth or decline); (b) the composition of the population; and (c) the distribution of population in space. It deals with five "demographic processes", namely fertility, mortality, marriage, migration and social mobility. These five processes are continuously at work within a population determining size, composition and distribution.

Community medicine is vitally concerned with population, because health in the group depends upon the dynamic relationship between the numbers of people, the space which they occupy and the skill that they have acquired in providing for their needs. The main sources of demographic statistics in India are population censuses, National Sample Surveys, registration of vital events, and ad hoc demographic studies.

Demographic cycle

The history of world population since 1650 suggests that there is a demographic cycle of 5 stages through which a nation passes:

(1) FIRST STAGE (High stationary)

This stage is characterized by a high birth rate and a high death rate which cancel each other and the population remains stationary. India was in this stage till 1920.

(2) SECOND STAGE (Early expanding)

The death rate begins to decline, while the birth rate remains unchanged. Many countries in South Asia, and Africa are in this phase. Birth rates have increased in some of these countries possibly as a result of improved health conditions, and shortening periods of breast-feeding (1).

(3) THIRD STAGE (Late expanding)

The death rate declines still further, and the birth rate tends to fall. The population continues to grow because births exceed deaths. India has entered this phase. In a number of developing countries (e.g., China, Singapore) birth rates have declined rapidly.

(4) FOURTH STAGE (Low stationary)

This stage is characterized by a low birth and low death rate with the result that the population becomes stationary. Zero population growth has already been recorded in Austria during 1980–85. Growth rates as little as 0.1 were recorded in UK, Denmark, Sweden and Belgium during 1980–85. In short, most industrialized countries have undergone a demographic transition shifting from a high birth and high death rates to low birth and low death rates.

(5) FIFTH STAGE: (Declining)

The population begins to decline because birth rate is lower than the death rate. Some East European countries, notably Germany and Hungary are experiencing this stage.

WORLD POPULATION TRENDS

At the beginning of the Christian era, nearly 2,000 years ago, world population was estimated to be around 250 million. Subsequent estimates of the world population, and rates of increase are given in Table 1.

It required all the human history up to the year 1800 for the world population to reach one billion. The second billion came in 130 years (around 1930), the third billion in 30 years (around 1960), the fourth billion in 15 years (in 1974), the fifth billion in 12 years (in 1987), and the sixth billion in 12 years (1999). On October 12th 1999 world population became 6 billion. The 7th billion came in 2014 (after 15 years). It is expected to reach 8 billion by 2025 (2).

About three fourths of the world's population lives in the developing countries. The population of the ten most populous countries of the world and their relative share is shown in Fig. 1. Although, in terms of population USA ranks
third in the world after India, there is a yawning gap of 1032 million between the population of these two countries.

The United Nations has estimated that world's population grew at an annual rate of 1.23 per cent during 2000-2010. China registered a much lower annual growth rate of population (0.6 per cent) during 2002-2012, as compared to India (1.4 per cent). In fact, the growth rate of China is now very much comparable to that of USA (0.9 per cent).

Three countries of SEAR, i.e. India (1359 million), Indonesia (267 million) and Bangladesh (167 million) are among the most populous ten countries of the world. At present India's population is second to that of China. According to UN projections India's population will reach 1.53 billion by the year 2050, and will be the highest population country in the world. The trend of population increase in South East Asia Region countries is as shown in Table 2.

Source: (3, 4)

In all these countries, key factors in fertility decline included changes in government attitudes towards growth, the spread of education, increased availability of contraception and the extension of services offered through family planning programmes, as well as the marked change in marriage patterns.

Death rates have also declined worldwide over the last decades. The global death rate declined from 11.0 (between 1975-1980) to 7 per thousand population during 2018, a reduction of 23 per cent. The decline in the death rate of the South-East Asia Region has been more marked, from 14.1 to 7.0 per 1000 population.

In countries with a relatively young population, crude death rates are mainly affected by infant and child mortality. With improvement in maternal and child health services, successful implementation of the expanded programme on immunization, diarrhoeal disease and acute respiratory infection control programmes, as well as with the control of other infectious diseases, there has been marked reduction
in infant and child mortality rates, which are reflected in the declining crude death rates.

Growth rates

When the crude death rate is subtracted from the crude birth rate, the net residual is the current annual growth rate, exclusive of migration. The relation between the growth rate and population increase is as shown in Table 5.

Source: (5)

It is said that population growth rates, like railway trains, are subject to momentum. They start slowly and gain momentum. Once in motion, they take time to bring the momentum under control. In case of the train, the control factors are mass and inertia; in population, they are age distribution, marriage customs and numerous cultural, social and economic factors.

The world population growth rate was at, or near its peak, around 1970, when the human population grew by an estimated 1.92 per cent. The most recent data show a slight decline since then to 1.2 per cent in 2018.

The growth rate is not uniform in the world. There are many countries in the world (e.g., European countries) where the growth rate is less than 0.3 per cent per year. In developing countries, the growth rates are excessive - it is around 2.6 per cent in Africa, 1.1 per cent in Latin America, 0.3 per cent in Europe and industrialized countries, and 1.5 per cent in Asia. A population growing at 0.5 per cent per year will double in about 140 years, a population growing at 3 per cent per year will double in about 20-25 years (Table 5). These differences in growth rates are largely the result of fertility and mortality patterns. The salient features of population growth at a glance are as follows:

- Approximately 95 per cent of this growth is occurring in the developing countries
- Currently, one-third of the world's population is under the age of 15, and will soon enter the reproductive bracket, giving more potential for population growth.
- The UNFPA estimates that world population is most likely to reach 10 billion people by 2050, and 20.7 billion a century later.
- The expected number of births per women, at current fertility rates (2016) is: for industrialized countries 1.6, developing countries 2.8 and for least developed countries 4.2. The global total fertility rate is 2.4.

The rampant population growth has been viewed as the greatest obstacle to the economic and social advancement of the majority of people in the underdeveloped world.

---

**DEMOGRAPHIC TRENDS IN INDIA**

**Demographic indicators**

Demographic characteristics provide an overview of its population size, composition, territorial distribution, changes therein and the components of changes such as nativity, mortality and social mobility. Demographic indicators have been divided into two parts - population statistics and vital statistics.

**Population statistics** include indicators that measure the population size, sex ratio, density and dependency ratio.

**Vital statistics** include indicators such as birth rate, death rate, natural growth rate, life expectancy at birth, mortality and fertility rates.

These indicators help in identifying areas that need policy and programmed interventions, setting near and far-term goals and deciding priorities, besides understanding them in an integrated structure.

With a population of 1,359 million in the year mid 2018, India is the second most populous country in the world, next only to China, whereas seventh in land area. With only 2.4 per cent of the world's land area, India is supporting about 17.5 per cent of the world's population. The population of India since 1901, average annual exponential growth rate (%), and the decadal growth of population (%) is as shown in Table 6.

**DEMOGRAPHY AND FAMILY PLANNING**
India's population has been steadily increasing since 1921. The year 1921 is called the “big divide” because the absolute number of people added to the population during each decade has been on the increase since 1921 (Table 6). India’s population is currently increasing at the rate of 16 million each year.

India's population numbered 238 million in 1901, doubled in 60 years to 439 million (1961); doubled again, this time in only 30 years to reach 846 million by 1991. It crossed 1 billion mark on 11 May 2000, and is projected to reach 1.53 billion by the year 2050. This will then make India the most populous country in the world, surpassing China.

With the division of some states the rank of most populous states have changed. Table 7 shows the ten most populous states in the country by rank. It is seen that Uttar Pradesh comes first with about 199.581 million people. Maharashtra comes second with 112.372 million people and Bihar comes third with 103.804 million people. These ten states account for about 71 per cent of the total population of India (6).

Source: (6)

It has been estimated that with current trends, the population in India will increase from 1.210 billion to 1.4 billion during the period 2011 to 2026. There is a substantial difference in total fertility rate in between and within states. At one end of spectrum are southern states like Kerala, Tamil Nadu, Karnataka and Andhra Pradesh with total fertility rate at or below replacement levels. At the other end are high fertility states like Uttar Pradesh, Chhattisgarh, Uttarakhand, Rajasthan, Jharkhand, Bihar, Madhya Pradesh and Orissa, with an estimated total fertility rate of more than 2.2.

The Government of India has categorized states according to total fertility rate (TFR) level into very high focus (more than or equal to 3.0), high focus (more than 2.1 and less than 3.0) and non-high focus (less than or equal to 2.1) categories. The states categorized as very high-focus and high focus are as follows (7):

- **TFR 2.2-3.0**: Assam - 2.3, Dadra & Nagar Haveli - 2.3, Mizoram - 2.3, Chhattisgarh - 2.5, Jharkhand - 2.6, Manipur - 2.6, Rajasthan - 2.7, Nagaland - 2.7, Madhya Pradesh - 2.8
- **TFR more than or equal to 3.0**: Bihar - 3.3, Uttar Pradesh - 3.1 and Meghalaya - 3.0

It is matter of concern that these states will delay the attainment of replacement level of fertility in India. These high fertility states are anticipated to contribute about 50 per cent to the nation-wide increase in population. Demographic outcomes in these states will determine the timing and size of population at which India achieves population stabilization.

### Age and sex composition

The age-sex composition of India’s population is as shown in Table 8. In the age group 0–14 years male population is about 0.4 per cent more than female, whereas in the age group 60+ , percentage of female population is 0.7 per cent more than male population. The proportion of population in the age group 0–14 years is higher in rural areas (28.6 per cent) than in urban areas (23.6 per cent), for both male and female population (8).

The proportion of population below 14 years of age is showing decline, whereas the proportion of elderly in the country is increasing. This trend is to continue in the time to come. The increase in the elderly population will impose a greater burden on the already outstretched health services in the country.

### Age pyramids

The age structure of a population is best represented as shown in Fig. 2.

Such a representation is called an “Age Pyramid”. A vivid contrast may be seen in the age distribution of men and women in India and in Switzerland. The age pyramid of India is typical of developing countries, with a broad base and a tapering top. In the developed countries, as in Switzerland, the pyramid generally shows a bulge in the middle, and has a narrower base.
Sex ratio

Sex ratio is defined as “the number of females per 1000 males”. One of the basic demographic characteristics of the population is the sex composition. In any study of population, analysis of the sex composition plays a vital role. The sex composition of the population is affected by the differentials in mortality conditions of males and females, sex selective migration and sex ratio at birth. “Female deficit syndrome” is considered adverse because of social implications. A low sex ratio indicates strong male-child preference and consequent gender inequities, neglect of the girl child resulting in higher mortality at younger age, female infanticide, female foeticide, higher maternal mortality and male bias in enumeration of population. Easy availability of sex determination tests and abortion services may also be proving to be catalyst in the process, which may be further stimulated by preconception sex selection facilities.

The trends in the sex ratio in the country from 1901 onwards are as shown in Table 9.

Source: (6)

The sex ratio in India has been generally adverse to women, i.e., the number of women per 1000 men has generally been less than 1000. Apart from being adverse to women, the sex ratio has also declined over the decades.

**Sex ratio at birth**: Sex ratio at birth can be affected by sex-selectivity at birth. The sex ratio at birth for India for the year 2014–2016 has been estimated at 898. It varies from 902 in rural areas to 888 in urban areas. Among the bigger states, the sex ratio at birth varies from 963 in Chhattisgarh to 832 in Haryana. In the rural areas, the highest and lowest sex ratio at birth are in the states of Chhattisgarh (995) and Haryana (835) respectively. The sex ratio in urban areas varies from 957 in Madhya Pradesh to 820 in Gujarat. Table 10 shows the variations of sex ratio at birth by residence in the bigger states of the country.

Source: (8)
Child sex ratio (0–6 years) : Census 2011 marks a considerable fall in child sex ratio in the age group of 0–6 years and has reached an all time low of 914 since 1961. The fall has been 13 points from 927 to 914 for the country during 2001 to 2011. In rural areas, the fall has been significant - 15 points from 934 to 919 and in urban areas it has been 4 points from 906 to 902 over the decade (6).

Dependency ratio

The proportion of persons above 65 years of age and children below 15 years of age are considered to be dependant on the economically productive age group (15–64 years). The ratio of the combined age groups 0–14 years plus 65 years and above the 15–65 years age group is referred to as the total dependency ratio. It is also referred to as the societal dependency ratio and reflects the need for a society to provide for their younger and older population groups. The dependency ratio can be subdivided into young age dependency ratio (0–14 years); and old age dependency ratio (65 years and more). These ratios are, however, relatively crude, since they do not take into consideration elderly or young persons who are employed or working age persons who are unemployed. It is given by the formula:

\[
\text{Total dependency ratio} = \frac{\text{Children 0–14 years age + Population more than 65 years of age}}{\text{Population of 15 to 64 years}} \times 100
\]

For India, the dependency ratio for the year mid 2016 is calculated as:

- Population in 0–14 years age group = 350,485,869
- Population above 65 years of age = 79,928,887
- Population in 15–64 years age group = 851,521,155

\[
\text{Total dependency ratio} = \frac{350,485,869 + 79,928,887}{851,521,155} \times 100 = 40.546 \text{ per cent}
\]

The young age dependency ratio is 41.115 per cent, and old age dependency ratio is 9.386 per cent for the year Jan. 2018 (9).

For international comparison, the child, old and total dependency ratios are used to study the dependency burden of the population. The total dependency ratio tends to decrease in the earlier stages of development when rapid decline in fertility reduces the child population more than the increase in the older persons, but subsequently the increase in older persons far out-weighs the decline in the child population. There is a shift from child dependency to old age dependency, as fertility declines and life expectancy increases.

The rapid decline in dependency ratios, especially the child dependency ratio, has been identified to be a key factor underlying rapid economic development. The term “demographic bonus” connotes the period when the dependency ratio in a population declines because of decline in fertility, until it starts to rise again because of increasing longevity. This period depends on the pace of decline in fertility level of a population. If the switch to small families is fast, the demographic bonus can give a considerable push to development. If investment in health care and education for skill development are made during this period, maximum advantage is taken of the demographic transition with high economic growth rates (10).

The term “demographic burden” is used to connote the increase in the total dependency ratio during any period of time, mostly caused by increased old age dependency ratio. This is an inevitable consequence of demographic transition, and the country has to face this problem sooner or later (10).

Density of population

One of the important indices of population concentration is the density of population. It is the ratio between (total) population and surface (land) area. This ratio can be calculated for any territorial unit for any point in time, depending on the source of the population data (10). In the Indian census, density is defined as the number of persons living per square kilometre. The trends of the density in the country from 1901 onwards are as shown in Table 11. For the year 2016 (July) the density of population per sq. km. in India was 401.4

Urbanization

By definition, urban population is the number of persons residing in urban localities. The definition of urban locality varies from country to country. In Indian context, the urban areas are the “towns (places with municipal corporation, municipal area committee, town committee, notified area committee or cantonment board); also, all places having 5,000 or more inhabitants, a density of not less than 1,000 persons per square mile or 390 per square kilometre, pronounced urban characteristics and at least three fourths of the adult male population employed in pursuits other than agriculture” (10).

The population in India continues to be predominantly rural with agriculture as the main occupation for the majority of the people.

As per population totals of Census — 2011, the rural population stands at 833.1 million (68.84 per cent) and urban population at 377.1 million (31.16 per cent), an increase of 3.35 per cent in urban population. In absolute numbers, rural population has increased by 90.47 million and urban population by 91.00 million in the last decade. Uttar Pradesh has the largest rural population of 155.11 million i.e. 18.62 per cent of country’s rural population, whereas Maharashtra has the highest urban population of 50.83 million i.e. 13.48 per cent of the country’s urban population. Fig. 3 indicates the level of urbanization in the country.

In the year 2017, the urban population of India was 33.5 per cent and the rural population stands at 66.5 per cent. The annual urbanization increase was 2.8 per cent (9).
The increase in urban population has been attributed both to natural growth (through births) and migration from villages because of employment opportunities, attraction of better living conditions and availability of social services such as education, health, transport, entertainment etc. The continuous migration of people from country side to urban areas in India constitute a social crisis, the ramification of which may eventually impair the quality of life.

According to 2011 census, the urban-rural scenario in India is as follows:

<table>

Family size

While in common parlance, family size refers to the total number of persons in a family, in demography, family size means the total number of children a woman has borne at a point in time (11). The completed family size indicates the total number of children borne by a woman during her child-bearing age, which is generally assumed to be between 15 and 45 years. The total fertility rate gives the approximate magnitude of the completed family size.

The family size depends upon numerous factors, viz. duration of marriage, education of the couple, the number of live births and living children, preference of male children, desired family size, etc.

The question of family size is undoubtedly important from the demographic point of view. The family planning programme’s campaign is currently based on the theme of a “two-child” family norm, with a view to reach the long-term demographic goal of NRR=1. Family planning involves both decision regarding the “desired family size” and the effective limitation of fertility once that size has been reached.

Table 12 shows the total fertility rates (completed family size) in India and selected countries. The decrease in family size does not appear to be due to any reduction in fertility: rather it appears to be due to the result of deliberate family planning.

**Literacy and education**

In 1948, the Declaration of Human Rights stated that everyone has a right to education. Yet, even today, this right is being denied to millions of children. Education is a crucial element in economic and social development. Without education, development can neither be broad based nor sustained. The benefits that accrue to a country by having a literate population are multidimensional. Spread of literacy is generally associated with modernization, urbanization, industrialization, communication and commerce. It forms an important input in the overall development of individuals enabling them to comprehend their social, political and cultural environment better, and respond to it appropriately. Higher levels of education and literacy lead to a greater awareness and also contribute to improvement of economic conditions, and is a pre-requisite for acquiring various skills and better use of health care facilities.

It was decided in 1991 census to use the term literacy rate for the population relating to seven years age and above. A person is deemed as literate if he or she can read and write with understanding in any language. A person who can merely read but cannot write is not considered literate. The same concept has been continued in census 2001 and 2011 also. The literacy rate taking in account the total population in the denominator has now been termed as "crude literacy rate", while the literacy rate calculated taking into account the 7 years and above population in the denominator is called the effective literacy rate. The formula for computing crude literacy rate and effective literacy rate are as follows:
LITERACY AND EDUCATION

Crude literacy rate = \( \frac{\text{Number of literate persons \times 100}}{\text{Total population in a given year}} \)

Effective literacy rate = \( \frac{\text{Number of literate persons aged 7 and above \times 100}}{\text{Population aged 7 and above in a given year}} \)

A significant milestone reached in Census 2011 is that the total number of illiterates has come down from 304.1 million in 2001 to 272.9 million in 2011 showing a decline of 31.1 million. The reverse trend was noted during 1991-2001 period. The decadal increase in the number of literates among males is of 31.9 per cent points and the corresponding increase among females is of 49.1 per cent points (6). These two changes are a clear indication that the gender gap in literacy is shrinking in the country. It will have far reaching consequence on the development of the society.

Table 13 shows the literacy rates in different states in India. The national percentage of literates in the population above 7 years of age is about 74.04 with literate males about 82.14 per cent and females lagging behind with about 65.46 per cent.

Table 13 shows that Kerala continues to occupy the top rank in the country with about 93.91 per cent literates. Mizoram (91.58 per cent, and Lakshadweep (92.28 per cent) closely follow Kerala. On the other end is Bihar and Arunachal Pradesh with literacy rate of only 63.82 and 66.9 per cent respectively. The states which have literacy rates below the national average are Arunachal Pradesh, Andhra Pradesh, Bihar and Jharkhand, Jammu & Kashmir, Uttar Pradesh, Madhya Pradesh, Rajasthan and Odisha etc.

The national average of literacy rate is misleading as wide variations exist between the states. Table 13 shows the literacy rates in different states in India. The national percentage of literates in the population above 7 years of age is about 74.04 with literate males about 82.14 per cent and females lagging behind with about 65.46 per cent.

Table 13 shows that Kerala continues to occupy the top rank in the country with about 93.91 per cent literates. Mizoram (91.58 per cent, and Lakshadweep (92.28 per cent) closely follow Kerala. On the other end is Bihar and Arunachal Pradesh with literacy rate of only 63.82 and 66.9 per cent respectively. The states which have literacy rates below the national average are Arunachal Pradesh, Andhra Pradesh, Bihar and Jharkhand, Jammu & Kashmir, Uttar Pradesh, Madhya Pradesh, Rajasthan and Odisha etc.

The Government of India has made education compulsory up to the age of 14 years in the country. Though considerable progress has been made in expanding primary education, a major concern is high drop out rates in the first few years of schooling (2).

Life expectancy

Life expectancy – or expectation of life – at a given age is the average number of years which a person of that age may expect to live, according to the mortality pattern prevalent in that country. Demographers consider it as one of the best indicators of a country’s level of development and of the overall health status of its population.
Life expectancy at birth has continued to increase globally over the years. For 1950-1955, the combined life expectancy at birth for both sexes was 46.5 years. Five decades later by 2008, it was 69 years — an increase of 22.5 years. The increase has been more marked in less developed regions of the world than in the developed regions (12).

Most countries in the world exhibit a sex differential in mortality favouring women — females live longer than males as shown in Table 14 and 15.

Trends in life expectancy show that people are living longer, and they have a right to a long life in good health, rather than one of pain and disability. Health policy makers thus need to recognize this changing demographic pattern and plan for prevention and control of diseases associated with old age.

Tables 14 and 15 present life expectancy at birth in India and those in selected countries, Japan leads in life expectancy for both males and females, 81 and 87 years respectively for the year 2017.

**FERTILITY**

By fertility is meant the actual bearing of children. Some demographers prefer to use the word natality in place of fertility. A woman’s reproductive period is roughly from 15 to 45 years — a period of 30 years. A woman married at 15 and living till 45 with her husband is exposed to the risk of pregnancy for 30 years, and may give birth to 15 children, but this maximum is rarely achieved.

Fertility depends upon several factors. The higher fertility in India is attributed to universality of marriage, lower age at marriage, low level of literacy, poor level of living, limited use of contraceptives and traditional ways of life. National Family Health Survey-4 conducted in India during 2015-2016 provides some detailed information of fertility trends, as shown in Table 16.

Source: (17)

Some of the factors which have engaged attention of demographers since long are discussed below.

1. **Age at marriage**

The age at which a female marries and enters the reproductive period of life has a great impact on her fertility. The Registrar General of India collected data on fertility on a national scale and found that females who marry before the age of 18 gave birth to a larger number of children than those who married after (18). In India some demographers have estimated that if marriages were postponed from the age of 16 to 20–21, the number of births would decrease by 20–30 per cent (18).
Early marriage is a long-established custom in India. As early as 1929, the Sarada Act was enacted forbidding the practice of child marriage. The census data reveals that prior to 1951, the average age at marriage for girls in India was 13 years. There is, however, a gradual rise in the age at marriage in the country. The Child Marriage Restraint Act of 1978 raises the legal age at marriage from 15 to 18 years for girls, and from 18 to 21 years for boys. Studies indicate that in many States, the mean age at marriage for girls has already moved up to 20 years in 2006, and many others are very close to this. For the year 2016, the national average for effective marriage is 22.3 years. The exceptions are the rural areas, where a substantial proportion of marriages continue to take place when the girl is around 16 years of age (8).

2. Duration of married life

Studies indicate that 10-25 per cent of all births occur within 1-5 years of marriage; 50-55 per cent of all births within 5-15 years of marriage. Births after 25 years of marriage are very few (18). This suggests that family planning efforts should be concentrated in the first few years of married life in order to achieve tangible results.

3. Spacing of children

Studies have shown that when all births are postponed by one year, in each age group, there was a decline in total fertility. It follows that spacing of children may have a significant impact on the general reduction in the fertility rates.

4. Education

There is an inverse association between fertility and educational status. Education provides knowledge; increased exposure to information and media; builds skill for gainful employment; increases female participation in family decision making; and raises the opportunity costs of women’s time. The National Family Health Survey-4 shows that the total fertility rate is 1.07 children higher for illiterate women than for women with at least a high school education (Table 16).

5. Economic status

Operational Research studies support the hypothesis that economic status bears an inverse relationship with fertility. The total number of children born declines with an increase in per capita expenditure of the household. The World Population Conference at Bucharest in fact stressed that economic development is the best contraceptive. It will take care of population growth and bring about reductions in fertility.

6. Caste and religion

Muslims have a higher fertility than Hindus. The National Family Health Survey-4 reported a total fertility rate of 2.61 among Muslims as compared to 2.13 among Hindus. The total fertility rate among Christians was found to be 1.99. Among Hindus, the lower castes seem to have a higher fertility rate than the higher castes (17).

7. Nutrition

There appears to be some relationship between nutritional status and fertility levels. Virtually, all well-fed societies have low fertility, and poorly-fed societies have high fertility. The effect of nutrition on fertility is largely indirect.

8. Family planning

Family planning is an important factor in fertility reduction. In a number of developing countries, family planning has been a key factor in declining fertility (Table 4). Family planning programmes can be initiated rapidly and require only limited resources, as compared to other factors.

9. Other factors

Fertility is affected by a number of physical, biological, social and cultural factors such as place of women in society, value of children in society, widow remarriage, breast-feeding, customs and beliefs, industrialization and urbanization, better health conditions, housing, opportunities for women and local community involvement. Attention to these factors requires long-term government programmes and vast sums of money.

FERTILITY-RELATED STATISTICS

Fertility may be measured by a number of indicators, as given below. Stillbirths, foetal deaths and abortions, however, are not included in the measurement of fertility in a population (19).

1. Birth Rate

Birth rate is the simplest indicator of fertility and is defined as “the number of live births per 1000 estimated mid-year population, in a given year”. It is given by the formula:

\[
\text{Birth Rate} = \frac{\text{Number of live births during the year}}{\text{Estimated mid-year population}} \times 1000
\]

The birth rate is an unsatisfactory measure of fertility because the total population is not exposed to child bearing. Therefore it does not give a true idea of the fertility of a population.

2. General Fertility Rate (GFR)

It is the “number of live births per 1000 women in the reproductive age group (15-44 or 49 years) in a given year”,

\[
\text{GFR} = \frac{\text{Number of live births in an area during the year}}{\text{Mid-year female population age 15-44 (or 49) in the same area in same year}} \times 1000
\]

General fertility rate is a better measure of fertility than the crude birth rate because the denominator is restricted to the number of women in the child-bearing age, rather than the whole population. The major weakness of this rate is that not all women in the denominator are exposed to the risk of childbirth.

3. General Marital Fertility Rate (GMFR)

It is the “number of live births per 1000 married women in the reproductive age group (15-44 or 49 years) in a given year”,

\[
\text{GMFR} = \frac{\text{Number of live births in a year}}{\text{Mid-year married female population in the age-group 15-49 years}} \times 1000
\]
4. Age-specific Fertility Rate (ASFR)
A more precise measure of fertility is age-specific fertility rate, defined as the "number of live births in a year to 1000 women in any specified age-group". The age-specific fertility rates throw light on the fertility pattern. They are also sensitive indicators of family planning achievement.

\[
\text{ASFR} = \frac{\text{Number of live births in a particular age group}}{\text{Mid-year female population of the same age group}} \times 1000
\]

5. Age-specific Marital Fertility Rate (ASMFR)
It is the number of live births in a year to 1000 married women in any specified age group.

\[
\text{ASMFR} = \frac{\text{Number of live births in a particular age group}}{\text{Mid-year married female population of the same age group}} \times 1000
\]

6. Total Fertility Rate (TFR)
Total fertility rate represents the average number of children a woman would have if she were to pass through her reproductive years bearing children at the same rates as the women now in each age group (20). It is computed by summing the age-specific fertility rates for all ages; if 5-year age groups are used, the sum of the rates is multiplied by 5. This measure gives the approximate magnitude of "completed family size".

\[
\text{TFR} = \frac{\sum_{15-49} \text{ASFR}}{1000}
\]

7. Total Marital Fertility Rate (TMFR)
Average number of children that would be born to a married woman if she experiences the current fertility pattern throughout her reproductive span.

\[
\text{TMFR} = \frac{\sum_{15-49} \text{ASMFR}}{1000}
\]

8. Gross Reproduction Rate (GRR)
Average number of girls that would be born to a woman if she experiences the current fertility pattern throughout her reproductive span (15-44 or 49 years), assuming no mortality.

\[
\text{GRR} = \frac{\sum_{15-49} \text{ASFR for female live births}}{1000}
\]

9. Net Reproduction Rate (NRR)
Net Reproduction Rate (NRR) is defined as the number of daughters a newborn girl will bear during her lifetime assuming fixed age-specific fertility and mortality rates (21).

NRR is a demographic indicator. NRR of 1 is equivalent to attaining approximately the 2-child norm. If the NRR is less than 1, then the reproductive performance of the population is said to be below replacement level.

10. Child-woman Ratio
It is the number of children 0-4 years of age per 1000 women of child-bearing age, usually defined as 15-44 or 49 years of age. This ratio is used where birth registration statistics either do not exist or are inadequate. It is estimated through data derived from censuses (6).

11. Pregnancy Rate
It is the ratio of number of pregnancies in a year to married women in the ages 15-44 (or 49) years. The "number of pregnancies" includes all pregnancies, whether these had terminated as live births, stillbirths or abortions or had not yet terminated.

12. Abortion Rate
The annual number of all types of abortions, usually per 1000 women of child-bearing age (usually defined as age 15-44) (22).

13. Abortion Ratio
This is calculated by dividing the number of abortions performed during a particular time period by the number of live births over the same period (23).

14. Marriage Rate
It is the number of marriages in the year per 1000 population:

\[
\text{Crude Marriage Rate} = \frac{\text{Number of marriages in the year}}{\text{Mid-year population}} \times 1000
\]

Demographers consider this a very unsatisfactory rate, because the denominator is comprised primarily of population that is not eligible to marry. A more sensitive rate is the general marriage rate:

\[
\text{General Marriage Rate} = \frac{\text{Number of marriages within one year}}{\text{Number of unmarried persons age 15-49 years}} \times 1000
\]

This rate is more accurate when computed for women than for men because more men than women marry at the older ages (6).

**Fertility trends**
Researches indicate that the level of fertility in India is beginning to decline. The crude birth rate which was about 49 per thousand population during 1901-11 has declined to about 25.0 per thousand population in 2002, and was 20.4 per thousand population in 2016. The rural urban differential has narrowed. However, the crude birth rate has continued to be higher in rural areas as compared to urban areas in the last 3 decades.

The total fertility rate has declined from 3.6 in 1991 to 2.3 in 2016. The TFR in rural areas has declined from 5.4 in 1971 to 2.5 in 2016, whereas the corresponding decline in urban areas has been from 4.1 to 1.8 during the same period. There are considerable inter-state variations in total fertility rate as shown in Fig. 5. In bigger states it varies from 1.6 in Tamil Nadu to 3.3 in Bihar (8).
now being canvassed for men as a special project, on a voluntary basis under the family welfare programme. Under the project, medical personnel all over the country are to be trained. Availability of this new technique at the peripheral level will increase the acceptance of male sterilization in the country. The project is being funded by the UNFPA (96).

Female sterilization

Female sterilization can be done as an interval procedure, postpartum or at the time of abortion. Two procedures have become most common, namely laparoscopy and minilaparotomy.

(a) Laparoscopy

This is a technique of female sterilization through abdominal approach with a specialized instrument called “laparoscope”. The abdomen is inflated with gas (carbon dioxide, nitrous oxide or air) and the instrument is introduced into the abdominal cavity to visualize the tubes. Once the tubes are accessible, the Faloipe rings (or clips) are applied to occlude the tubes. This operation should be undertaken only in those centres where specialist obstetrician–gynaecologists are available. The short operating time, shorter stay in hospital and a small scar are some of the attractive features of this operation.

Patient selection: Laparoscopy is not advisable for postpartum patients for 6 weeks following delivery; however, it can be done as a concurrent procedure to MTP. Haemoglobin per cent should not be less than 8. There should be no associated medical disorders such as heart disease, respiratory disease, diabetes and hypertension. It is recommended that the patient be kept in hospital for a minimum of 48 hours after the operation.

The cases are required to be followed-up by health workers (F) LHVs in their respective areas once between 7–10 days after the operation, and once again between 12 and 18 months after the operation.

Complications: Although complications are uncommon, when they do occur they may be of a serious nature requiring experienced surgical intervention. Puncture of large blood vessels and other potential complications have been reported as major hazards of laparoscopy.

(b) Minilap operation

Minilaparotomy is a modification of abdominal tubectomy. It is a much simpler procedure requiring a smaller abdominal incision of only 2.5 to 3 cm conducted under local anaesthesia. The minilap/Pomeroy technique is considered a revolutionary procedure for female sterilization. It is also found to be a suitable procedure at the peripheral level will increase the acceptance of male sterilization in the country. The project is being funded by the UNFPA (96).

Evaluation of contraceptive methods

Contraceptive efficacy is generally assessed by measuring the number of unplanned pregnancies that occur during a specified period of exposure and use of a contraceptive method. The two methods that have been used to measure contraceptive efficacy are the Pearl index and life-table analysis.

The Pearl index is defined as the number of “failures per 100 woman-years of exposure (HWY).” This rate is given by the formula:

\[
\text{Failure rate per HWY} = \frac{\text{Total accidental pregnancies}}{\text{Total months of exposure}} \times 1200
\]

In applying the above formula, the total accidental pregnancies shown in the numerator must include every known conception, whatever its outcome, whether this had terminated as live births, still-births or abortions or had not yet terminated. The factor 1200 is the number of months in 100 years. The total months of exposure in the denominator is obtained by deducting from the period under review of 10 months for a full-term pregnancy, and 4 months for an abortion (97).

A failure rate of 10 per HWY would mean that in the lifetime of the average woman about one-fourth or 2.5 accidental pregnancies would result, since the average fertile period of a woman is about 25 years (97).

In designing and interpreting a use-effectiveness trial, a minimum of 600 months of exposure is usually considered necessary before any firm conclusion can be reached (97).

With most methods of contraception, failure rates decline with duration of use. The Pearl Index is usually based on a specific exposure (usually one year) and, therefore, fails to accurately compare methods at various durations of exposure. This limitation is overcome by using the method of life-table analysis.

Life-table analysis: Life-table analysis calculates a failure rate for each month of use. A cumulative failure rate can then compare methods for any specific length of exposure. Women who leave a study for any reason other than unintended pregnancy are removed from the analysis, contributing their exposure until the time of the exit.

Element of success in family planning programme

The main strategy of family planning programme is to offer to client easy access to a wide range of affordable contraceptive method through multiple service delivery channels in a good quality, reliable fashion. The key points are as follows: (1) Make services accessible: Offering services through a variety of delivery points makes methods available to more potential users; (2) Make services affordable: Partnerships between public and private-sector services encourage clients to pay what they can, while public programmes serve the poor for free or for low fees; (3) Offer client-centered care: Planning and providing services with the clients in mind help to make sure their needs are met and their preferences are honoured; (4) Rely on evidence-based technical guidance: Up-to-date service delivery guidelines, tools, and job aids can help translate research findings into better practice; (5) Communicate effectively: Communication grounded in behaviour theory and sensitive to local norms motivates clients to seek services and helps them make good family planning choices; (6) Assure contraceptive security: A strong logistics system and a long-term plan for contraceptive security ensure that a variety of methods, and the supplies and equipment to provide them, are always available; (7) Work for supportive policies: Showing how family planning contributes to development.
goals makes the case for continued support for family planning programme; (8) Coordinate: When governments, donor agencies, and implementing partners work together, they streamline efforts and avoid duplication; (9) Build a high-performing staff: Programme can keep workers motivated and on the job by creating a good working environment, matching skills with tasks, and rewarding a job well done; (10) Secure adequate budget, use it well: Spending wisely, doing more with less, and finding ways to recover costs can help ensure financial sustainability; (11) Base decisions on evidence: Research, monitoring, and evaluation yield important information to guide decision-making, and they need not be expensive; (12) Lead strongly, manage well: Strong leadership helps programmes navigate change. Good management solves operational problems, and (13) Integrate services appropriately: Programmes can address a wider range of health needs by integrating services where appropriate and offering referrals where it is not

**Unmet need for family planning (111)**

The concept that eventually became unmet need for family planning was first explored in 1960s, when data from surveys of contraceptive knowledge attitude and practices (KAP) showed a gap between some women's reproductive intention and their contraceptive behaviour. The term that came to popular use describing this group was “KAP-gap”. One of the first published use of the term “unmet need” appeared in 1977. In 1978, based on World Fertility Survey data from five Asian countries, Charles Westoff published first comparative estimates of unmet need for limiting births

Many women who are sexually active would prefer to avoid becoming pregnant, but nevertheless are not using any method of contraception (including use by their partner). These women are considered to have an “unmet need” for family planning. The concept is usually applied to married women. However, it can apply to sexually active fecund women and perhaps to men, but its measurement has been limited to married women only. Unmet need can be a powerful concept for family planning. It poses a challenge to family planning programme - to reach and serve millions of women whose reproductive attitude resembles those of contraceptive user - but who are, for some reason or combination of reasons, not using contraceptives.

Among the most common reason for unmet need are inconvenient or unsatisfactory services, lack of information, fears about contraceptive side-effects and opposition from husband or relatives. Unmet need is defined on the basis of women's response to survey questions.

According to the National Family Health Survey-4, the unmet need for family planning is highest (22.2 per cent) among women between 15 to 24 years of age and is almost entirely for spacing the births rather than for limiting the births. The unmet need for contraception among women aged 30 years and above are mostly for limiting the births.

Unmet need for family planning is higher in rural areas than in urban areas. It also varies by women's education (within range of 11–17 per cent) and religion (Hindu and Christian women have a lower unmet need than Muslim women). Table 24 shows some of the characteristics of unmet need for family planning in India (17).

The National Family Health Survey-4 results show that although current use of contraception has increased and the extent of unmet need has declined in most of the states in India, there is a need for considerable improvement in the coverage and quality of family planning services, especially in the four large states of Uttar Pradesh, Bihar, Madhya Pradesh and Rajasthan.

**Contraception and adolescence (112)**

Adolescence is the period between puberty and the end of physiological maturation, which occurs between ages 15–19 years. Pregnancy in adolescence constitutes about 11 per cent of all pregnancies in most developing countries and in some developed countries such as the USA. For the year 2014, WHO puts the global adolescent birth rate at 49 per 1000 girls of that age, country rates range from one to 229 births per 1000 girls. This indicates a marked decrease since 1990 (113). These are often "at risk" pregnancies. Many are undesired, and occur in unmarried
adolescents who then resort to legal or illegal abortion, performed under unsatisfactory medical conditions. This has serious health and even life-threatening consequences for these young women – the ensuing mortality and morbidity (especially secondary sterility) are quite considerable.

Prevention of undesired pregnancies and of sexually transmitted diseases in young people through educational programmes dealing with responsible sexual behaviour is a major public health challenge. Adolescents are ambivalent about family planning; to request contraception is to "reveal" one's sexuality. For this reason, adolescent girls sometimes choose the risk of an undesired pregnancy and an abortion.

**BARRIER METHODS** : Condoms make barrier methods worthwhile, because they protect those adolescents, with occasional different sexual partners, against STD and AIDS. However, condoms must be properly used, and it depends on the man's behaviour. Young men seem to be increasingly aware of the importance of safeguarding their own health and that of their partners. Cervical caps and diaphragms, on the other hand, are inappropriate for adolescents since they require foreseeing of intercourse and complicated manipulations, to which young people are loath.

**HORMONAL CONTRACEPTION** : Hormonal methods are perfectly suitable for adolescents, who generally do not suffer from such problems as cardiovascular contraindications. In fact, these are probably the most adequate methods, since they are completely reversible, and in no way modify the future fertility of these young women. In developed countries, pills are usually preferred, but trimestrial or monthly injections are also appropriate. Implants, with their five year term, cover too long a period for certain adolescents.

**IUD** : IUD are theoretically contraindicated, because of the risk of pelvic infection and of secondary sterility. However, an adolescent is better protected by an IUD than by illegal repeated abortions. This method has the advantage of being discrete and avoiding demanding routines.

**OTHER METHODS** : Periodic abstinence is not easy when cycles are irregular and intercourse is unforeseen, and with new partners. In certain countries, however, they are practically the only method taught, for religious reasons, and poor protection is preferable to no protection at all. Similarly, withdrawal is not very suitable method, since young men are usually not very skillful.

Spermicides are not contraindicated, but have two disadvantages – they are costly, and are not effective against STD and AIDS.

As a major chunk of the world population is under 25 years age group. An extremely large number of young people will, therefore, be entering their reproductive years at that time. The demographic future of the world will depend on them, on how well informed they are, and on their sense of responsibilities.

## DELIVERY SYSTEM

Since family planning is essentially a component of the health care system, the primary responsibility for the delivery of services rests with the Government through its health care system at the Centre and in the States.

### At the Centre

The Family Welfare Programme is a centrally sponsored scheme, and the states receive 100 per cent assistance from the central government. Since the entire cost is virtually borne by the central government, the central government controls the planning, and financial management of the programme (e.g., establishment of clinics, pattern of staffing, expenditure); training, research and evaluation, and most important, the formulation of an overall policy for the programme. The current policy is to promote family planning on the basis of voluntary and informed acceptance with full community participation. The emphasis is on a 2-child family. Recently there have been two major changes in the approach to delivery of family planning services: first, a greater emphasis on spacing methods, side by side with terminal methods, and secondly to take the services to every door-step and motivate families to adopt the small family norm.

The administrative apparatus consists of a separate Department of Family Welfare, which was created in 1965 in the Central Ministry of Health and Family Welfare. The Secretary to the Government of India in the Ministry of Health and Family Welfare is in charge of the Department of Family Welfare. He is assisted by a Special Secretary and Joint Secretaries. The special secretary supervises the programme implementation and coordinates the various activities. There is now an Advisor (Mass Media and Communication) – an officer of the rank of an Additional Secretary. The National Institute of Health and Family Welfare acts as an apex technical institute for promoting health and family welfare in the country through education, training services, research and evaluation. There is a Central Family Welfare Council consisting of all the State Health Ministers to review the implementation of the programme. A Population Advisory Council headed by the Union Health Minister, Members of Parliament, and persons from the fields related to population control was set up in 1982. This body acts as a "think tank" to analyze the implementation of the programme and advise the government suitably. A cabinet sub-committee headed by the Prime Minister has also been formed for periodic review of the progress of the family welfare programme. Family planning is no longer viewed as the sole responsibility of the Health Ministry, but will devolve on all ministries connected with human resources and development. This is an important breakthrough in current thinking.

### At the State level

Under the Indian constitution, the state governments are responsible for the administration and implementation of the Family Welfare Programme. Since most of the crucial policy decisions are made by the central government, the pattern of organization and many features of the delivery system are fairly well-standardized in the States.

The organizational set-up at the State level consists of a State Family Welfare Bureau, which is part of the State Health and Family Welfare Directorate. At present, 25 State Family Welfare Bureaus are functioning in the country.

In 1979, the offices of the Family Welfare and National Malaria Eradication Programme were merged into one office and named as Regional Office for Health and Family Welfare. These regional offices have been set up to maintain liaison with state governments and give technical assistance to them in connection with the implementation of the Family Welfare Programme and other important health programmes. To co-ordinate the family welfare activities between the state governments and the central government, one Family Welfare Cell has been sanctioned for each State.
At the district level

At the district level, the set-up consists of a District Family Welfare Bureau consisting of 3 divisions – an administrative division headed by the District Family Welfare Officer; mass education and media division, in charge of District Mass Education and Media Officer, and an evaluation division, in charge of a Statistical Officer. These are supported by 1.083 Urban Family welfare centres and 871 Urban Health Posts. Presently there are 4 types of Urban Health Posts—type A for areas with population less than 5,000, type B for areas with population between 5,000–10,000, type C for population between 10,000–25,000, and type D for areas with population between 25,000–50,000. If the population is more than 50,000, then it is to be divided into sectors of 50,000 population and Health Posts provided. Type A, B and C Health Posts are attached to a hospital for providing referral and supervisory services. Type D Health Post is attached to a hospital for sterilization, MTP and referral (34). Only type D health post have a post of medical officer.

The 10 city family welfare bureaus are entrusted with the responsibility of coordination, monitoring and supervision etc. of the family welfare services provided by various institutions in the city.

Presently there are three types of Urban Family Welfare Centres. Type I is for population between 10,000–25,000, type II is for population between 25,000–50,000, and type III is for above 50,000 population (34). These are manned by 2 para-medical staff in type I and II centres and by 6 persons including medical officer in type III centres.

The Urban family welfare centres and health posts provide comprehensive integrated services of MCH and family planning. The staff pattern is different for different types of health posts and urban family welfare centres

At the community health centre

Community health centre is established and maintained by the state governments. Presently it is manned by four medical specialists i.e. surgeon, physician, gynaecologist and paediatrician, supported by 21 paramedical and other staff. It has 30 in-door beds with one OT, X-ray, labour room and laboratory facilities and serves as a referral centre for four PHCs. According to Indian Public Health Standards, the community health centre is to be manned by 6 medical specialists including an anaesthetist and an eye surgeon supported by 24 paramedical and other staff with inclusion of two nurse midwives. It provides, apart from other emergency obstetric care, full range of family planning services including laparoscopic services and safe abortion services. At present as of March 2015, 5,396 community health centres are functional in the country (34A).

At the primary health centre

Since more than 68.2 per cent of India’s population lives in the rural areas an adequate network of service centres has been extended to the rural areas. A Rural Family Welfare Centre with a medical officer and supporting staff forms an integral part of the primary health centre. A total of 5,435 Rural Family Welfare Centres were established in the country at all block level PHCs sanctioned upto 1.4.1980. Most of the states have integrated these centres into their primary health care system and after this date family planning services are being provided through Integrated facilities at PHCs (34A). As of March 2017, 25,650 primary health centres were functioning in the country. Each centre is supported by sub-centres. The total number of sub-centres functioning are 156,231.

When fully staffed (by 3 medical officers including one lady doctor and supporting personnel) the PHC is expected to provide fairly comprehensive “essential health care” including family planning care. The medical officers are usually trained to provide MTP and sterilization services. The programme of insertion of copper-T IUDs has been intensified. It is intended that laparoscopic services which have become very popular will be made more widely available at the PHC.

The sub-centres are to provide the main thrust of the programme. Each subcentre is staffed by one male and one female health worker. They are responsible for providing rudimentary health and MCH care; family planning motivation, supplies and services in spacing methods

Various studies conducted have highlighted that the existing infrastructure is not being optimally utilized because of its inadequacy to provide proper services. To improve matters popular committees have been set up at all levels by some states to involve people in the programme and in exercising vigilance over the work of various functionaries

At the village level

Two schemes are being implemented at the village level to improve the outreach of services and increase local participation: (a) The Village Health Guides : An innovative approach has been the creation of a band of village Health Guides (mostly women), one for each village or a population of 1000. They are made responsible for spreading knowledge and information to the eligible couples and providing them with supplies of Nirodh and oral pills. About 3.23 lakh health guides are in position. (b) Trained dais : The national target is to provide one trained dai per 1000 population. They conduct safe deliveries in rural areas. They also act as family planning counsellors and motivators, supplementing the delivery system. (c) ASHA : 9.15 lakh ASHAs have been selected so far and have been provided with drug kits (34A). At present the village health guides, trained dais and ASHAs are the lynchpins of the family planning delivery system in India

New initiatives (114)

1. Home Delivery of Contraceptives (HDC)
   a. A new scheme has been launched to utilise the services of ASHA to deliver contraceptives at the doorstep of beneficiaries. The scheme was launched in 233 pilot districts of 17 States on 11 July 2011 and is now expanded to the entire country from 17th December 2012.
   b. ASHA is charging a nominal amount from beneficiaries for her effort to deliver contraceptives at doorstep i.e. Rs. 1 for a pack of 3 condoms. Rs.1 for a cycle of OCPs and Rs. 2 for a pack of one tablet of ECP

2. Ensuring spacing at birth (ESB)
   a. Under a new scheme launched by the Government of India, services of ASHAs to be utilized for counselling newly married couples to ensure spacing of 2 years after marriage and couples with 1 child to have spacing of 3 years after the birth of 1st child. The scheme is operational in 18 States (EAG, North-Eastern and Gujarat and Haryana). ASHA would be paid following incentives under the scheme:

DeMOGRAPHY AND FAMILY PLANNING
- Rs. 500/- to ASHA for delaying first child birth by 2 years after marriage.
- Rs. 500/- to ASHA for ensuring spacing of 3 years after the birth of 1st child.
- Rs. 1000/- in case the couple opts for a permanent limiting method upto 2 children only.

b. Ministry of Health & Family Welfare has introduced short term IUCD (5 years effectively), Cu IUCD 375 under the National Family Planning programme. Training of State level trainers has already been completed and process is underway to train service providers up-to the sub-centre level.

c. A new method of IUCD insertion (post-partum IUCD insertion) has been introduced by the Government.

d. Promoting Post-partum Family Planning services at district hospitals by providing for placement of dedicated Family Planning Counsellors and training of personnel.

3. Pregnancy Testing Kits

Nischay-Home based pregnancy test kits (PTKs) was launched under NRHM in 2008 across the country. The PTKs are being made available at sub-centres and to the ASHAs to facilitate the early detection and decision making for the outcomes of pregnancy.

4. Mission Parivar Vikas (MPV)

A programme launched in 146 high total fertility rate districts to accelerate the use and awareness of family planning methods. States and districts fact sheet highlight the current indicators and trends in these districts and will act as baseline and roadmap for future work in these districts. A five pronged strategy has been developed under the mission parivar vikas, which comprises (7):

a. Delivering assured services;

b. Building additional capacity/human resources development for enhanced service delivery;

c. Ensuring commodity security;

d. Implementing new promotional schemes; and

e. Creating an enabling environment.

5. New contraceptive launch (7)

The new contraceptive injectable MPA under “Antara programme” and oral contraceptive pill centchroman “chhaya” have been added to the existing contraceptive basket of choice thus providing the users with new options.

The public sector provides a wide range of contraceptive services for limiting and spacing of births at various levels of health system as described in Table 25.
Community Needs Assessment Approach (115)

Till recently, the achievements of family welfare programme were assessed on the basis of the targets given from the centre for individual contraceptives. This led to a situation where the achievement of the contraceptive targets had become the ends by themselves. Over the years it became apparent that there were many drawbacks in the top down target approach in which types and quantity of contraceptive need to be canvassed was decided by the higher authorities. Firstly, the user preference was not reflected in the targets. If the contraceptive required in accordance with the user was not available, the targets were not likely to be achieved. There was no authentic system of feedback regarding which type of contraceptive was to be promoted in a particular area or among a particular age group. Secondly, the quality of the services became secondary. For example, if in an attempt to fulfill targets for the number of IUD insertions, the quality of care is compromised (especially while screening women for pre-existing reproductive tract infections and sexually transmitted diseases before IUD insertion) the acceptability of IUD programme would receive a serious setback and discontinuation rate will be high. Thirdly, people may be tempted to resort to false reporting to claim fulfillment of the target. In other words, contraceptive targets and cash incentives resulted in the inflation of performance statistics and deterioration in the quality of services.

Government of India deliberated objectively on the utility of retaining the practice of targets at national and state levels. In the year 1995-96, one district in each of 18 states (including a pilot project in Kerala and Tamil Nadu) were made target free. Later on the practice of fixing up of targets for individual contraceptive method was given up from April 1996. This does not mean a licence to do no work. The population goals remain the same as before. Health workers are expected to consult families and local community in the beginning of the year in order to assess their needs and preference and then work-out for themselves the programme and workload for the coming year. The requirement for each village needs to be worked out to arrive at the workload for the ANM, this becomes the target for the ANM for the year. The workload of different ANMs under one PHC when added up would determine the workload for the PHC. Similarly requirements at the district level would be worked out by adding up the requirements at all the PHCs.

Later on it was found that due to complex calculations required the health workers were unable to fix the performance norms for themselves. Therefore, it was decided to modify and rename the target free manual as Community Needs Assessment Approach Manual.

Involvement of private sector

The family planning programme, to be successful, will have to be extended beyond the government delivery system to include the private sector. Grants-in-aid are provided to voluntary organizations and industrial organizations for running family welfare centres and postpartum centres. The scheme for involvement of private medical practitioners in the family welfare programme has been extended to practitioners of integrated medicine. Government has also created nation-wide retail outlets for selling subsidized condoms.

Incentives and dis-incentives

The use of incentives and dis-incentives to encourage couples to practise family planning has become a common strategy in many developing countries. Financial compensation of individuals undergoing sterilization was first introduced in 1966; over the years, it has been gradually increased. The acceptors now receive a one-time payment as follows (7):

National Family Planning Indemnity Scheme (NFPIIS)

With effect from, 01.04.2013, it has been decided that States/UTs would process and make payment of claims to accepters of sterilization in the event of death/failures/complications/indemnity cover to doctors/health facilities. The States/UTs would make suitable budget provisions for implementation of the scheme through their respective State/UT Programme Implementation Plans (PIPs) under the National Rural Health Mission (NRHM) and the scheme is renamed as “Family Planning Indemnity Scheme”.

State government employees, who undergo sterilization after two or three children are eligible for a special increment (two increments after 2 children and one after 3 children). Central government employees get one increment after sterilization. It is under the scheme introduced in Dec. 1979 to promote small family norm, provided the employee is below 50 years of age and his spouse below 45 years. They get special leave (14 days for women and 7 days for men). No maternity leave is allowed after 3 children.

The State Governments have been requested to: issue Green Cards to individual acceptors of terminal methods after two children as a mark of recognition and for priority attention in schemes where preferential treatment was feasible. Cash awards have been instituted for the best performing states, the amount of which will be spent on promoting family welfare activities (116)

Family welfare linked health insurance scheme (96)

Government of India has introduced a family planning insurance scheme for acceptors of sterilization and indemnity cover for doctors performing sterilization procedures in both government and accredited private/NGO corporate health facilities. The insurance scheme will be operated by the ICICI.

Compensation in the event of death:

In the event of death following sterilization (inclusive of death during process of sterilization operation) in hospital or within 7 days from the date of discharge from the hospital, the compensation available as stated above.

All the doctors and health facilities rendering family planning services, conducting such operations shall stand indemnified against claims arising out of failure of sterilization, death or medical complications resulting there-from up to a maximum amount of Rs 2 lacs per doctor/health facility per case. The cover would also include the legal costs and actual modality of defending the prosecuted doctor/health facility in court, which would be borne by the insurance company within certain limits (117).

Postpartum Programme (118)

An All India Hospital Postpartum Programme (AIHPP) was introduced in 1969. It is a hospital-based, maternity centred approach to family planning. The primary objective of the postpartum programme is to improve the health of the mother and children through MCH and Family Welfare programme which includes antenatal, neonatal, and postnatal services; immunization services to children and mothers; and prophylaxis against anenemia and blindness.

The programme is based on the following rationale:

a. That women who have recently delivered are of proven fertility, and are at risk to become pregnant again rapidly.

b. At the time of delivery and during the lying-in period, they are generally more receptive to adopt one or the other family planning method.

The postpartum programme offers necessary facilities to such women. It has proved to be an efficient way of
delivering family planning services. The programme now covers 550 medical institutions at national, state and district levels inclusive of 100 medical colleges and 2 post-graduate institutions. A scheme of PAP smear test facilities has been sanctioned for all medical colleges.

With a view to provide MCH and family welfare services in rural and semi-urban areas, as well as to improve the health of mothers and children, the postpartum programme has been extended to sub-divisional and sub-district hospitals. 1,012 such centres are functioning in the country (119).

Population education

Population education has been defined as “an educational programme which provides for a study of the population situation in the community, nation and world with the purpose of developing in the students rational and responsible attitudes and behaviour towards that situation” (118). The content of population education programme is influenced by the specific national situation as well as by political and educational goals (120).

In the Indian context, the concept of population education is designed to bring home to the students, both at school and university level the consequences of uncontrolled population growth; the benefits of a small family norm; the economics, sociology and statistics of population growth, its distribution and its relation to the levels of living.

SOCIIOLOGY OF FAMILY PLANNING

The institution of family is as old as man himself. It is the basic social cell. The need for its discipline has only recently dawned because of changing economic, social and cultural patterns in the world – and above all, because of concern of what might be called “quality of life” criteria. Sociologists and economists have shown that it will be difficult to raise the living standards of the people while population growth continues unchecked. The gains of the five year developmental plans are being absorbed by the rapidly growing population for basic consumption, e.g., food, shelter, clothing, education and medical care.

Attitude surveys have shown that awareness of family planning is very widespread and over 60 per cent people have attitudes favourable to restricting or spacing births (27). People are generally in favour of family planning, and there is no organized opposition to it. Inspite of this, the rate of contraceptive use by couples in the developing countries is very low. This is the crux of the family planning problem. Studies have shown that the population problem is complicated by deep-rooted religious and other beliefs, attitudes and practices favouring larger families (e.g., strong preference for male children). The common beliefs are – that children are the gift of God; the number of children is determined by God; children are an asset to which parents can look forward in periods of dependency caused by old age or misfortune, etc. Most of these beliefs stem from ignorance and lack of communication.

The problem of family planning is, therefore, essentially the problem of social change. Contraceptive technology is no short cut to the problem. What is more important is to stimulate social changes affecting fertility such as raising the age of marriage, increasing the status of women, education and employment opportunities, old age security, compulsory education of children, accelerating economic changes designed to increase the per capita income, etc. It is now axiomatic that economic development is the best contraceptive. The experience of all countries which have had a successful population control show that the best motivation is economic, a desire to improve standard of living. The solution to the problem is one of mass education and communication, so that people may understand the benefits of a small family.

VOLUNTARY ORGANIZATIONS

Voluntary organizations have played a major role in population control programmes since the beginning. They are involved in every possible way so as to complement governmental efforts to promote Family Welfare Programme. Apart from educational and motivational efforts, their activities include running of Family Welfare Centres, post-partum centres, ANM training schools, population research centres and other innovative projects.

Some of the well-known voluntary agencies in India are the Family Planning Association of India, the Family Planning Foundation and the Population Council of India. Others include the Indian Red Cross, the Indian Medical Association, Rotary Clubs, Lions Clubs, Citizens Forum, Christian Missionaries and Private Hospitals.

At the international level, the International Planned Parenthood Federation is the world’s largest private voluntary organization supporting family planning services in developing countries. It is an international federation of independent Family Planning Associations with headquarters in London. Others with long experience in this field include the United Nations Fund for Population Activities (UNFPA), the US Agency for International Development (USAID), the Population Council, Ford Foundation, the Pathfinder Fund and World Bank besides WHO and UNICEF. The international agencies are assisting in funding family planning research, services, training and information programmes designed to reduce the family size.

NATIONAL FAMILY WELFARE PROGRAMME

India launched a nation-wide family planning programme in 1952, making it the first country in the world to do so, though records show that birth control clinics have been functioning in the country since 1930. The early beginnings of the programme were modest with the establishment of a few clinics and distribution of educational material, training and research. During the Third Five Year Plan (1961–66), family planning was declared as “the very centre of planned development”. The emphasis was shifted from the purely “clinic approach” to the more vigorous “extension education approach” for motivating the people for acceptance of the “small family norm”. The introduction of the Lippes Loop in 1965 necessitated a major structural reorganization of the programme, leading to the creation of a separate Department of Family Planning in 1966 in the Ministry of Health. During the years 1966–1969, the programme took firmer roots. The family planning infrastructure (e.g., primary health centres, sub-centres, urban family planning centres, district and State bureaux) was strengthened. During the Fourth Five Year Plan (1969–74), the Government of India gave “top priority” to the programme. The Programme was made an integral part of MCH activities of PHCs and their sub-centres. In 1970, an All India Hospital Postpartum Programme and in 1972, the Medical Termination of Pregnancy (MTP) Act were
introduced. During the Fifth Five Year Plan (1975–80) there
have been major changes. In April 1976, the country framed
its first “National Population Policy”. The disastrous forcible
sterilization campaign of 1976 led to the Congress defeat in
the 1977 election. In June 1977, the new (Janata)
Government that came into power formulated a new
population policy, ruling out compulsion and coercion for all
times to come. The Ministry of Family Planning was
renamed “Family Welfare”.

Although the performance of the programme was low
during 1977–78, it was a good year in as much as the
programme moved into new healthier directions. The 42nd
Amendment of the Constitution has made “Population
control and Family Planning” a concurrent subject, and this
provision has been made effective from January 1977. The
acceptance of the programme is now purely on voluntary
basis. The launching of the Rural Health Scheme in 1977 and
the involvement of the local people (e.g., Health Guides,
trained Dais, Opinion leaders) in the family welfare
programme at the grass-root level were aimed at accelerating
the pace of progress of the programme. India was a signatory
to the Alma Ata Declaration in 1978. The acceptance of
the primary health care approach to the achievement of HFA/2000 AD led to the formulation of a National Health Policy in
1982. The National Health Policy was approved by the
Parliament in 1983. It laid down the long-term demographic
goal of NRR=1 by the year 2000 – which implies a 2-child
family norm – through the attainment of a birth rate of 21 and
a death rate of 9 per thousand population, and a couple
protection rate of 60 per cent by the year 2000. The Sixth
and Seventh Five Year Plans were accordingly set to achieve
these goals. The National Health Policy also called for restructuring the health care delivery system to achieve HFA/2000 AD, and
family planning has been accorded a central place in health
development.

The Universal Immunization Programme aimed at
reduction in mortality and morbidity among infants and
younger children due to vaccine preventable diseases was
started in the year 1985–86. The oral rehydration therapy
was also started in view of the fact that diarrhoea was a
leading cause of death among children. Various other
programmes under MCH were also implemented during the
Seventh Five Year Plan. The objective of all these
programmes were convergent and aimed at improving the
health of the mothers and young children, and to provide
them facilities for prevention and treatment of major
diseases. During 1992 these programmes were integrated
under Child Survival and Safe Motherhood (CSSM) Programme

The process of integration of related programmes
initiated was taken a step further during 1994 when the
International Conference on Population and Development
in Cairo recommended implementation of Unified
Reproductive and Child Health Programme (RCH). It is
obviously sensible that integrated RCH programme would
help in reducing cost of inputs to some extent because
overlapping of expenditure would no longer be necessary
and outcome will be better. Accordingly, during Ninth
Five Year Plan the RCH Programme integrates all the related
programmes of the Eighth Five Year Plan. The concept of
RCH is to provide need based, client oriented, demand
driven, high quality integrated services.

The Government of India evolved a more detailed
and comprehensive National Population Policy 2000 (see
page 544) to promote family welfare.

In the year 2005 Govt. of India launched National Rural
Health Mission, initially for seven years (2005–2012) which
was extended for 5 years up to 2017. Then came National
Urban Health Plan and merging both these plans as National
Health Mission. In the year 2013, RMNCH+A strategy was
launched which was based on a continuum of care approach
and defines integrated packages of services for different
stages of life. In the year 2014, India Newborn Action Plan
(INAP) came with the goal to attain single digit neonatal
mortality rate by 2030 and single digit stillbirth rate by 2030.

The investment on family welfare programme during
successive plan-periods is tabulated below (121). It can be
seen that from a modest sum of 0.65 crores during the first
plan, the investment has reached a colossal amount of
Rs. 371,600 crores during the Twelfth Plan period.

EVALUATION OF FAMILY PLANNING

Evaluation is defined as a “process of making judgements
about selected objectives and events by comparing them
with specified value standards for the purpose of deciding
alternative course of action”. The purpose of evaluation is
to improve the design and delivery of family planning services.

Five types of evaluation have been defined by a WHO
Expert Committee in 1975 (29) on evaluation of family
planning in health services:

1. Evaluation of need
That is, health, demographic and socio-economic needs
for family planning. For example, the current status of
maternal mortality in a given area is an indicator of the need
for family planning

2. Evaluation of plans
That is, an assessment of the feasibility and adequacy of
programme plans.

3. Evaluation of performance
(a) Services : Clinic services, mobile services, post-
partum services, contraceptive distribution, follow
up services, education and motivation activities:
(b) Response: Number of new acceptors, characteristics of acceptors;
(c) Cost analysis; and
(d) Other activities: Administration, manpower, data system, etc.

4. Evaluation of Effects

Changes in knowledge, attitudes, motivation and behaviour.

5. Evaluation of Impact

A WHO Study Group in 1976 (122) proposed the following indices for evaluating the impact: (a) Family size (number of living children) (b) desired number of additional children (c) birth interval (d) age of the mother at birth of first child and last child (e) birth order, and (f) number of abortions. To this may be added, changes in birth rate and growth rate.

Evaluation is a technical activity that requires trained personnel, statistical facilities and adequate flow of data and information.

The Family Welfare Programme in India has come a long way and holds forth the promise that in the not very distant future it may be accepted as a way of life by most people. Although birth control continues to occupy the same important position in the programme as it used to be in the earlier days the programme now aims at achieving a higher end – and that is, to improve, in conjunction with other development programmes, the quality of life of the people (121).

In any community, mothers and children constitute a priority group. In sheer numbers, they comprise approximately 71.14 per cent of the population of the developing countries. In India, women of the child-bearing age (15 to 44 years) constitute 22.2 per cent, and children under 15 years of age about 35.3 per cent of the total population. Together they constitute nearly 57.5 per cent of the total population. By virtue of their numbers, mothers and children are the major consumers of health services, of whatever form.

Mothers and children not only constitute a large group, but they are also a “vulnerable” or special-risk group. The risk is connected with child-bearing in the case of women; and growth, development and survival in the case of infants and children. Whereas 50 per cent of all deaths in the developed world are occurring among people over 70, the same proportion of deaths are occurring among children during the first five years of life in the developing world. Global observations show that in developed regions maternal mortality ratio averages at 12 per 100,000 live births; in developing regions the figure is 239 for the same number of live births (1). From commonly accepted indices, it is evident that infant, child and maternal mortality rates are high in many developing countries. Further, much of the sickness and deaths among mothers and children is largely preventable. By improving the health of mothers and children, we contribute to the health of the general population. These considerations have led to the formulation of special health services for mothers and children all over the world.

The problems affecting the health of mother and child are multifactorial. Despite current efforts, the health of mother and child still constitutes one of the most serious health problems affecting the community, particularly in the developing countries. The present strategy is to provide mother and child health services as an integrated package of “essential health care”, also known as primary health care which is based on the principles of equity, intersectoral coordination and community participation. The primary health care approach combines all elements in the local community necessary to make a positive impact on the health status of the population, including the health of mothers and children.

**Mother and child – one unit**

Mother and child must be considered as one unit. It is because: (1) during the antenatal period, the foetus is part of the mother. The period of development of foetus in mother is about 280 days. During this period, the foetus obtains all the building materials and oxygen from the mother’s blood. (2) child health is closely related to maternal health. A healthy mother brings forth a healthy baby; there is less chance for a premature birth, stillbirth or abortion; (3) certain diseases and conditions of the mother during pregnancy (e.g., syphilis, German measles, drug intake) are likely to have their effects upon the foetus; (4) after birth, the child is dependant upon the mother. At least up to the age of 6 to 9 months, the child is completely dependant on the mother for feeding. The mental and social development of the child is also dependant upon the mother. If the mother dies, the child’s growth and development are affected (maternal deprivation syndrome); (5) in the care cycle of women, there are few occasions when service to the child is not simultaneously called for. For instance, postpartum care is inseparable from neonatal care and family planning advice; and (6) the mother is also the first teacher of the child. It is for these reasons, the mother and child are treated as one unit.

**Obstetrics, Paediatrics and Preventive and Social Medicine**

In the past, maternal and child health services were rather fragmented, and provided piecemeal “personal health services” by different agencies, in different ways and in separate clinics. The current trend in many countries is to provide integrated MCH and family planning services as compact family welfare service. This implies a close relationship of maternity health to child health, of maternal and child health to the health of the family; and of family health to the general health of the community. In providing these services, specialists in obstetrics and child health (paediatrics) have joined hands, and are now looking beyond the four walls of hospitals into the community to meet the health needs of mothers and children aimed at positive health. In the process, they have linked themselves to preventive and social medicine, and as a result, terms such as “social obstetrics”; “preventive paediatrics” and “social paediatrics” have come into vogue.

**OBSTETRICS**

Obstetrics is largely preventive medicine. The aim of obstetrics and preventive medicine is the same, viz. to ensure that throughout pregnancy and puerperium, the mother will have good health and that every pregnancy may culminate in a healthy mother and a healthy baby. The age-old concept that obstetrics is only antenatal, intranatal and postnatal care, and is thus concerned mainly with technical skills, is now considered as a very narrow concept, and is being replaced by the concept of community obstetrics which combines obstetrical concerns with concepts of primary health care.
SOCIAL OBSTETRICS

The concept of social obstetrics has gained currency in recent years. It may be defined as the study of the interplay of social and environmental factors and human reproduction going back to the preconceptional or even premarital period. The social and environmental factors which influence human reproduction are legion, viz. age at marriage, child bearing, child spacing, family size fertility patterns, level of education, economic status, customs and beliefs, role of women in society, etc. A study of these factors is an important aspect of social obstetrics. The social obstetric problems in India, differ from the social obstetric problems in the developed countries, because of various differing social, economic, cultural and other factors. While accepting the influence of environmental and social factors on human reproduction, social obstetrics has yet another dimension, that is the influence of these factors on the organization, delivery and utilization of obstetric services by the community. In other words, social obstetrics is concerned with the delivery of comprehensive maternity and child health care services including family planning so that they can be brought within the reach of the total community (2).

Preventive paediatrics

Paediatrics which is synonymous with child health is that branch of medical science that deals with the care of children from conception to adolescence, in health and disease. Paediatrics is one of the first clinical subjects to link itself to preventive medicine. Like obstetrics, paediatrics has a large component of preventive and social medicine. There is no other discipline so comprehensive as paediatrics that teaches the value of preventive medicine. Recent years have witnessed further specialization within the broad field of paediatrics viz. preventive paediatrics, social paediatrics, neonatology, perinatology, developmental paediatrics, paediatric surgery; paediatric neurology, and so on.

Preventive paediatrics comprises efforts to avert rather than cure disease and disabilities. It has been broadly divided into antenatal paediatrics and postnatal paediatrics. The aims of preventive paediatrics and preventive medicine are the same: prevention of disease and promotion of physical, mental and social well-being of children so that each child may achieve the genetic potential with which he/she is born. To achieve these aims, hospitals for children have adopted the strategy of “primary health care” to improve child health care through such activities as growth monitoring, oral rehydration, nutritional surveillance, promotion of breastfeeding, immunization, community feeding, regular health check-ups, etc. Primary health care with its potential for vastly increased coverage through an integrated system of service delivery is increasingly looked upon as the best solution to reach millions of children, especially those who are most in need of preventive and curative services.

Social paediatrics

The challenge of the time is to study child health in relation to community, to social values and to social policy. This has given rise to the concept of social paediatrics. Social paediatrics has been defined as “the application of the principles of social medicine to paediatrics to obtain a more complete understanding of the problems of children in order to prevent and treat disease and promote their adequate growth and development, through an organized health structure (3)". Social paediatrics, like social obstetrics, covers a wide responsibility. It is concerned not only with the social factors which influence child health but also with the influence of these factors on the organization, delivery and utilization of child health care services. In other words, social paediatrics is concerned with the delivery of comprehensive and continuous child health care services and to bring these services within the reach of the total community. Social paediatrics also covers the various social welfare measures — local, national and international — aimed to meet the total health needs of a child.

Preventive and social medicine, with its involvement in total community care, and expertise in epidemiology and in the methodology of collection and utilization of data relating to the community and the environment, makes an indispensable contribution to social obstetrics and social paediatrics in the:

1. collection and interpretation of community statistics, delineating groups “at risk” for special care;
2. correlation of vital statistics (e.g., maternal and infant morbidity and mortality rates, perinatal and child mortality rates) with social and biological characteristics such as birth weight, parity, age, stature, employment etc. in the elucidation of pathological relationships;
3. study of cultural patterns, beliefs and practices relating to childbearing and childrearing, knowledge of which might be useful in promoting acceptance and utilization of obstetric and paediatric services by the community;
4. to determine priorities and contribute to the planning of MCH services and programmes; and
5. for evaluating whether MCH services and programmes are accomplishing their objectives in terms of their effectiveness and efficiency.

Hitherto, obstetrics, paediatrics and preventive and social medicine were operating in watertight compartments. The emergence of social paediatrics, social obstetrics and their association with preventive and social medicine are certainly new developments in contemporary medicine. In some Universities, a chair of social paediatrics has also been established. The increasing coming together of these disciplines augurs well for the provision of comprehensive mother and child health care and family planning services as a compact family welfare service.

Maternity cycle

The stages in maternity cycle are:

1. **Prenatal period**
   - Ovum
   - Embryo
   - Foetus
2. **Premature infant**
3. **Birth, full term**

**Fertilization**: 0 to 14 days
**Antenatal or prenatal period**: 14 days to 9 weeks
**Intranal period**: 9th week to birth
**Postnatal period**: from 28 to 37 weeks
**Average 280 days**

**PREVENTIVE PAEDIATRICS**
MCH problems

MCH problems cover a broad spectrum. At one extreme, the most advanced countries are concerned with problems such as perinatal problems, congenital malformations, genetic and certain behavioural problems. At the other extreme, in developing countries, the primary concern is reduction of maternal and child mortality and morbidity, spacing of pregnancies, limitation of family size, prevention of communicable diseases, improvement of nutrition and promoting acceptance of health practices. Currently, the main health problems affecting the health of the mother and the child in India, as in other developing countries, revolve around the triad of malnutrition, infection and the consequences of unregulated fertility (4). Associated with these problems is the scarcity of health and other social services in vast areas of the country together with poor socio-economic conditions.

1. MALNUTRITION

Malnutrition is like an iceberg; most people in the developing countries live under the burden of malnutrition. Pregnant women, nursing mothers and children are particularly vulnerable to the effects of malnutrition. The adverse effects of maternal malnutrition have been well documented — maternal depletion, low birth weight, anaemia, toxemias of pregnancy, postpartum haemorrhage, all leading to high mortality and morbidity. The effects of malnutrition are also frequently more serious during the formative years of life. Previously it was thought that malnutrition was largely concentrated in school age children, and in toddlers. Now it is realized that the intrauterine period of life is a very important period from the nutritional standpoint. Infants born with adequate birth weight have relatively low mortality even under poor environmental conditions. The next critical period of childhood is the period of weaning. Severe malnutrition coincides with the age at which babies are usually weaned. Susceptibility to infection and severity of illness are significantly less in well nourished, than in malnourished children. Nutrition protection and promotion is, therefore, an essential activity of MCH care.

Measures to improve the nutritional status of mothers and children may be broadly divided into direct and indirect nutrition interventions (4). Direct interventions cover a wide range of activities, viz., supplementary feeding programmes, distribution of iron and folic acid tablets, fortification and enrichment of foods, nutrition education, etc. Indirect nutrition interventions have still wider ramifications because they are not specifically related to nutrition. These include measures such as control of communicable diseases through immunization, improvement of environmental sanitation, provision of clean drinking water, family planning, food hygiene, education and primary health care. Nutritional surveillance is becoming increasingly important for identifying subclinical malnutrition, as it tends to be overlooked in both the mother and the child. The primary health worker (community worker) can play a vital role in improving the nutritional status of mothers and children.

2. INFECTION

Maternal infections may cause a variety of adverse effects such as foetal growth retardation, low birth weight, embroyopathy, abortion and puerperal sepsis. In industrial societies, the risk of the mother acquiring infections during pregnancy is relatively low, but in underdeveloped areas, the mother is exposed to significantly higher risks. Many women are infected with HIV, hepatitis B, cytomegalovirus, herpes simplex virus or toxoplasma during pregnancy. Furthermore, as many as 25 per cent of the women in rural areas suffer at least one bout of urinary infection (5).

As far as the baby is concerned, infection may begin with labour and delivery and increase as the child grows older. Children may be ill with debilitating diarrheal, respiratory and skin infections for as much as a third of their first year of life. In some regions, the situation is further aggravated by such chronic infections as malaria and tuberculosis. The occurrence of multiple and frequent infections may precipitate in the children a severe protein-energy malnutrition and anaemia. When the child becomes ill, traditions, beliefs and taboos enter into play; the indirect effect of infections may be more important than the direct one in traditional societies (5, 6).

Prevention and treatment of infections in mother and children is a major and important part of normal MCH care activity. It is now widely recognized that children in developing areas need to be immunized against nine infections — tuberculosis, diphtheria, whooping cough, tetanus, hepatitis B, haemophilus influenza type B, Japanese encephalitis in endemic states, measles and polio. Many countries, including India, have adopted the WHO Expanded Programme on Immunization as part of everyday MCH care. Tetanus toxoid application during pregnancy has also been taken up. Education of mothers in medical measures such as oral rehydration in diarrhoeal and febrile diseases is being tried. In addition, a good knowledge and practice of personal hygiene and appropriate sanitation measures, particularly in and around the home, are essential pre-requisites for the control of the most common infections and parasitic diseases.

3. UNCONTROLLED REPRODUCTION

The health hazards for the mother and the child resulting from unregulated fertility have been well recognized — increased prevalence of low birth weight babies, severe anaemia, abortion, antepartum haemorrhage and a high maternal and perinatal mortality, which have shown a sharp rise after the 4th pregnancy. Statistics have shown that in almost every country in the world, a high birth rate is associated with a high infant mortality rate and under-five death rate (Table 1).

SOURCE: 78.
Because family planning has a striking impact on the health of the mother and the child, a number of countries have integrated family planning in the MCH care activities. The introduction of new types of IUD; easier and safer techniques of pregnancy termination and female sterilization; oral pills and long-acting injectable medroxyprogesterone acetate (MPA) have contributed a good deal in the utilization of family planning services. In some countries, MCH programmes are extending their scope to include family-life education in schools. There is also an increasing acceptance of the role of traditional midwives and community health workers, with suitable training for the extension of family planning services to remote rural areas.

Maternal and child health

The term “maternal and child health” refers to the promotive, preventive, curative and rehabilitative health care for mothers and children, it includes the sub-areas of maternal health, child health, family planning, school health, handicapped children, adolescence, and health aspects of care of children in special settings such as day care (4). The specific objectives of MCH are (a) reduction of maternal, perinatal, infant and childhood mortality and morbidity; (b) promotion of reproductive health; and (c) promotion of the physical and psychological development of the child and adolescent within the family. The ultimate objective of MCH services is lifelong health (4).

Pregnancy detection

The simple way to confirm pregnancy in the first trimester is to conduct a urine examination using a pregnancy test kit. The kit detects pregnancy on the basis of presence of human chorionic gonadotrophin hormone in the urine. The test is performed soon after a missed period and is simple to perform. The pregnancy test should be offered to any women who is in reproductive age group and comes with a history of amenorrhoea or symptoms of pregnancy. The Government of India has made “Nischay” pregnancy test kit available across the country. Other test kits are also available in the market. The kit is provided to ASHA or other link workers and the women should be advised appropriately on the result of the test (9).

ANTENATAL CARE

Antenatal care (ANC) can be defined as the care provided by skilled health-care professionals to pregnant women and pregnant adolescent girls in order to ensure the best health conditions for both mother and baby during pregnancy. The components of ANC include: risk identification; prevention and management of pregnancy-related or concurrent diseases; health education and health promotion (10). ANC reduces maternal and perinatal morbidity and mortality both directly, through detections, and indirectly, through the identification of women and girls at increased risk of developing complications during labour and delivery, thus ensuring referral to an appropriate level of care (10).

Ideally this care should begin soon after conception and continue throughout pregnancy. In some countries, notification of pregnancy is required to bring the mother in the prevention care cycle as early as possible.

Objectives

The objectives of antenatal care are:

1. To promote, protect and maintain the health of the mother during pregnancy;
2. To detect “high-risk” cases and give them special attention;
3. To foresee complications and prevent them;
4. To remove anxiety and dread associated with delivery;
5. To reduce maternal and infant mortality and morbidity;
6. To teach the mother elements of child care, nutrition, personal hygiene, and environmental sanitation;
7. To sensitize the mother to the need for family planning, including advice to cases seeking medical termination of pregnancy; and
8. To attend to the under-fives accompanying the mother.

The above objectives are achieved by the following programme of health care services:

(1) Antenatal visits

Ideally the mother should attend the antenatal clinic once a month during the first 7 months; twice a month, during the next month; and thereafter, once a week, if everything is normal. A high proportion of mothers in India are from lower socio-economic group, and many of them are working women. Attendance at the antenatal clinic may mean loss of daily wages. Consequently, it is difficult for them to attend the antenatal clinic so often. In these cases, a minimum of 4 visits covering the entire period of pregnancy should be the target, as shown below:

The suggested schedule is as follows (9):

1st visit — within 12 weeks, preferably as soon as the pregnancy is suspected. For registration of pregnancy and first antenatal check-up.
2nd visit — between 14 and 26 weeks.
3rd visit — between 28 and 34 weeks.
4th visit — between 36 weeks and term.

It is advisable for the woman to visit medical officer at the PHC for an antenatal check-up during the period of 28-34 weeks (3rd visit). Besides this, she may be advised to avail investigation facilities at the nearest PHC/CHC/FRU.

Registration of pregnancy within 12 weeks is the primary responsibility of the ANM. Opportunities such as Village Health Nutrition Day should be availed to ensure early registration of pregnancy and antenatal check-up.

Early pregnancy detection is important for the following reasons (9):

1. It facilitates proper planning and allows for adequate care to be provided during pregnancy for both the mother and the foetus.
2. Record the date of last menstrual period and calculate the expected date of delivery.
3. The health status of the mother can be assessed and any medical illness that she might be suffering from can be detected. Also to obtain and record the baseline information on blood pressure, weight, haemoglobin etc.
4. It helps in timely detection of complications at an early stage and helps to manage them appropriately by referral as and where required.
5. It also helps to confirm if the pregnancy is wanted and if not then refer the women at the earliest to a 24 hours PHC or FRU that provides safe abortion services. The health personnel should be alert to the possibility of sex selective abortion as such abortions are illegal.
6. Early detection of pregnancy and provision of care from the initial stage facilitates a good interpersonal relationship between the care giver and the pregnant woman.

Estimation of number of pregnancies in a specified area and pregnancy tracking (9)

To ensure complete registration, it is essential that the ANM should know the estimated number of pregnancies to be registered annually in her area. Calculating the expected number of annual pregnancies in the area will help her judge how good her pregnancy registration is. In case the number of pregnancies registered is less than that of the estimated pregnancies, she needs to track down the pregnancies she has missed, with the help of ASHAs and AWWs. Estimating the number of pregnancies will also help her judge whether she has an adequate stock of the supplies required to provide routine ANC (such as TT injections, IFA tablets and ANC record forms) and tackle any complications that arise during this period.

The number of expected pregnancies per year:

The ANM must know the population size and birth rate of the area under her jurisdiction. The expected number of live births may be calculated as shown below:

\[
\text{Expected no. of live births} = \frac{\text{Birth rate (per 1000 population) \times population of the area}}{1000}
\]

As some pregnancies may not result in a live birth (i.e. abortions and stillbirths may occur), the expected number of live births would be an under-estimation of the total number of pregnancies. Hence, a correction factor of 10% is required, i.e. add 10% to the figure obtained above.

So, the total number of expected pregnancies

\[(2) = Y + 10\% \text{ of } Y\]

As a thumb rule, in any given month, approximately half the number of pregnancies estimated above should be in records.

Example of estimation of the number of pregnancies annually

\[
\text{Birth rate} = \frac{25}{1000}\text{ population}
\]

\[
\text{Population under the sub-centre} = \text{5000}
\]

\[
\text{Therefore, expected number of live births} = \frac{(25 \times 5000)}{1000} = 125 \text{ births}
\]

\[
\text{Correction factor (pregnancy wastage)} = 10\% \text{ of } 125 = \text{say 13}
\]

\[
\text{Therefore, total no. of expected pregnancies in a year} = 125 + 13 = 138
\]

In any month, the ANM should have about 69 pregnancies registered with her.

If the number of women registered is less than expected the ANM should approach community leaders and key people to ensure that the pregnant women are registered and come for ANC. ASHA and link worker should visit every house in the area and ensure that all pregnant women are registered. Some women may be receiving ANC from the private sector. Ensure that their names together with the names of the facilities where they are registered are mentioned in the antenatal register.

The ANM must keep track of all pregnant women in her area. In case a registered woman does not turn-up for her ANC check-up, ANM must follow her and counsel her for the regular ANC check-up. An antenatal check-up after a missed appointment should include all the components of the missed visit(s) as well as those that correspond to the present visit. For example, the woman should be given her TT injection and supply of IFA tablets, her weight and blood pressure should be checked besides being screened for complications.

A policy decision has been taken for a name-based tracking system whereby pregnant women and children can be tracked for their ANCs and immunization along with a feedback system for the ANM, ASHA etc. This has been done to ensure that all pregnant women receive their ANCs and PNCs, and children receive full immunization. This will also help in tracking and ensuring ANC/PNC for missed/lost out cases.

PREVENTIVE SERVICES FOR MOTHERS (ANTENATAL CHECK-UP)

The first visit, irrespective of when it occurs, should include the following components:

I. History-taking

During the first visit, a detailed history of the woman needs to be taken to: (1) Confirm the pregnancy (first visit only); (2) Identify whether there were complications during any previous pregnancy/confinement that may have a bearing on the present one; (3) Identify any current medical/surgical or obstetric condition(s) that may complicate the present pregnancy; (4) Record the date of 1st day of last menstrual period and calculate the expected date of delivery by adding 9 months and 7 days to the 1st day of last menstrual period; (5) Record symptoms indicating complications, e.g., fever, persistent vomiting, abnormal vaginal discharge or bleeding, palpitation, easy fatigability, breathlessness at rest or on mild exertion, generalized swelling in the body, severe headache and blurring of vision, burning in passing urine, decreased or absent foetal movements etc; (6) History of any current systemic illness, e.g., hypertension, diabetes, heart disease, tuberculosis, renal disease, epilepsy, asthma, jaundice, malaria, reproductive tract infection, STD, HIV/AIDS etc. Record family history of hypertension, diabetes, tuberculosis, and thalassaemia. Family history of twins or congenital malformation; and (7) History of drug allergies and habit forming drugs.

II. Physical examination

1. Pallor: Presence of pallor indicates anaemia. The woman should be examined for pallor at each visit. Examine woman's conjunctiva, nails, tongue, oral mucosa and palms. Pallor should be co-related with haemoglobin estimation.

2. Pulse: The normal pulse rate is 60 to 90 beats per minute. If the pulse rate is persistently low or high, with or without other symptoms, the woman needs medical attention.

3. Respiratory rate: It is important to check the respiratory rate, especially if the woman complains of breathlessness. Normal respiratory rate is 18–20 breaths per minute.

4. Oedema: Oedema (swelling), which appears in the evening and disappears in the morning after a full night's sleep, could be a normal manifestation of pregnancy. Any oedema of the face, hands, abdominal wall and vulva is abnormal. Oedema can be suspected if a woman...
complies of abnormal tightening of any rings on her fingers. She must be referred immediately for further investigations. If there is oedema in association with high blood pressure, heart disease, anaemia or proteinuria, the woman should be referred to the medical officer.

5. **Blood pressure**: Measure the woman's blood pressure at every visit. This is important to rule out hypertensive disorders of pregnancy. Hypertension is diagnosed when two consecutive readings taken four hours or more apart show the systolic blood pressure to be 140 mmHg or more and or the diastolic blood pressure to be 90 mmHg or more. High blood pressure during pregnancy may signify Pregnancy-Induced Hypertension (PIH) and/or chronic hypertension. If the woman has high blood pressure, check her urine for the presence of albumin. The presence of albumin (+2) together with high blood pressure is sufficient to categorize her as having pre-eclampsia. Refer her to the MO immediately. If the diastolic blood pressure of the woman is above 110 mmHg, it is a danger sign that points towards imminent eclampsia. The urine albumin should be estimated at the earliest. If it is strongly positive, the woman should be referred to the FRU IMMEDIATELY. If the woman has high blood pressure but no urine albumin, she should be referred to the MO at 24x7 PHC. A woman with PIH, pre-eclampsia or imminent eclampsia requires hospitalization and supervised treatment at a 24-hour PHC.FRU.

6. **Weight**: A pregnant woman’s weight should be taken at each visit. The weight taken during the first visit registration should be treated as the baseline weight. Normally, a woman should gain 9–11 kg during her pregnancy. Ideally after the first trimester, a pregnant woman gains around 2 kg every month. If the diet is not adequate, i.e. if the woman is taking less than the required amount of calories, she might gain only 5–6 kg during her pregnancy. An inadequate dietary intake can be suspected if the woman gains less than 2 kg per month. She needs to be put on food supplementation. The help of the AWW should be taken in this matter, especially for those categories of women who need it the most. Low weight gain usually leads to Intrauterine Growth Retardation and results in the birth of a baby with a low birth weight. Excessive weight gain (more than 3 kg in a month) should raise suspicion of pre-eclampsia, twins (multiple pregnancy) or diabetes. Take the woman’s blood pressure and test her urine for proteinuria and sugar. If the blood pressure is high and the urine is positive for protein or sugar, refer her to medical officer.

7. **Breast examination**: Observe the size and shape of the nipples for the presence of inverted or flat nipples.

**III. Abdominal examination**

Examine the abdomen to monitor the progress of the pregnancy and foetal growth. The abdominal examination includes the following:

1. **Measurement of fundal height**: Enlargement of the uterus and the height of the uterine fundus is shown in Fig. 1.
   a. 12 weeks – Uterine fundus just palpable per abdomen
   b. 20 weeks – Fundus flat at the lower border of umbilicus
   c. 36 weeks – Fundus felt at the level of xiphisternum.

![](Figure1.png)

**Uterine fundal height at various stages of pregnancy**

(numbers indicate weeks of pregnancy)

**IV. Assessment of gestation age**

Measurement of gestational age has changed over the time. As the dominant effect of gestational age on survival and long-term impairment has become apparent over the last 30 years, perinatal epidemiology has shifted from measuring birth weight alone to focusing on gestational age. The most accurate “gold standard” for assessment is routine early ultrasound assessment together with foetal measurements ideally in the first trimester. Gestational age classification based on the date of last menstrual period (LMP) was previously the most widespread method used and remains the only available method in many settings. Many countries now use “best obstetric estimate”, combining ultrasound and LMP as an approach to estimate gestational age. It can have a large impact on the number of preterm births reported.

Any method using ultrasound requires skilled technicians, equipment and for maximum accuracy, first trimester antenatal clinic attendance. These are not common in low-income settings, where majority of preterm births occur. Alternative approaches to LMP in these settings include fundal height, clinical assessment of the newborn after birth or birth weight as a surrogate.
V. Laboratory investigations

The following laboratory investigations are carried out at the facilities indicated below:

a. At the sub-centre:
   - Pregnancy detection test
   - Haemoglobin examination.
   - Urine test for presence of albumin and sugar
   - Rapid malaria test.

b. At the PHC/CHC/FRU:
   - Blood group, including Rh factor.
   - VDRL/RPR
   - HIV testing.
   - Rapid malaria test (if unavailable at SC).
   - Blood sugar testing
   - HBsAg for hepatitis B infection.

Essential components of every antenatal check-up:

1. Take the patient's history.
2. Conduct a physical examination—measure the weight, blood pressure and respiratory rate and check for pallor and oedema
3. Conduct abdominal palpation for foetal growth, foetal lie and auscultation of foetal heart sound according to the stage of pregnancy
4. Carry out laboratory investigations, such as haemoglobin estimation and urine tests for sugar and proteins

Interventions and counselling

1. Iron and folic acid supplementation and medication as needed.
2. Immunization against tetanus.
3. Group or individual instruction on nutrition, family planning, self care, delivery and parenthood.
4. Home visiting by a female health worker/trained dai
5. Referral services, where necessary.
6. Inform the woman about Janani Suraksha Yojana and other incentives offered by the government.

RISK APPROACH (12)

The central purpose of antenatal care is to identify "high risk" cases (as early as possible) from a large group of antenatal mothers and arrange for them skilled care, while continuing to provide appropriate care for all mothers. The “risk approach” is a managerial tool for improved MCH care. Its purpose is to provide better services for all, but with special attention to those who need them most. Inherent in this approach is maximum utilization of all resources, including some human resources that are not conventionally involved in such care – traditional birth attendants, community health workers, women’s groups, for example. The risk strategy is expected to have far-reaching effects on the whole organization of MCH FP services and lead to improvements in both the coverage and quality of health care, at all levels, particularly at primary health care level.

MAINTENANCE OF RECORDS

A Mother and Child Protection Card should be duly completed for every woman registered. It contains a registration number, identifying data, previous health history and main health events etc. The case record should be handed over to the woman. She should be instructed to bring the record with her during all subsequent check-ups/visits and also to carry it along with her at time of delivery. This card has been developed jointly by the Ministry of Health and Family Welfare (MOHFW) and Ministry of Women and Child Development (MOWCD) to ensure uniformity in record keeping. This will also help the service provider to know the details of previous ANCs/PNCs both for routine and emergency care. The information contained in the card should also be recorded in the antenatal register as per the Health Management Information System (HMIS) format.

HOME VISITS

Home visiting is the backbone of all MCH services. Even if the expectant mother is attending the antenatal clinic regularly, it is suggested that she must be paid at least one home visit by the Health Worker Female or Public Health Nurse. More visits are required if the delivery is planned at home. The mother is generally relaxed at home. The home visit will win her confidence. The home visit will provide an opportunity to observe the environmental and social conditions at home and also an opportunity to give prenatal advice.

(2) Prenatal advice

A major component of antenatal care is antenatal or prenatal advice. The mother is more receptive to advice concerning herself and her baby at this time than at other times. The “talking points” should cover not only the specific problems of pregnancy and child-birth but overflow into family and child health care.

(i) DIET: Reproduction costs energy. A pregnancy in total duration consumes about 60,000 kcal, over and above normal metabolic requirements. Lactation demands about 550 kcal a day. Further, child survival is correlated with birth weight. And birth weight is correlated to the weight gain of the mother during pregnancy. On an average, a normal healthy woman gains about 9–11 kg of weight during pregnancy. Several studies have indicated that weight gain of poor Indian women averaged 6.5 kg during pregnancy (13). Thus pregnancy imposes the need for considerable extra calorie and nutrient requirements. If maternal stores of iron are poor (as may happen after repeated pregnancies) and if enough iron is not available to the mother during pregnancy, it is possible that foetus may lay down insufficient iron stores. Such a baby may show a normal haemoglobin at birth, but will lack the stores of iron necessary for rapid growth and increase in blood volume and muscle mass in the first year of life. Stress in the form of malaria and other childhood infections will make the
deficiency more acute, and many infants become severely anaemic during early months of life. A balanced and adequate diet is therefore, of utmost importance during pregnancy and lactation to meet the increased needs of the mother, and to prevent "nutritional stress."

(ii) PERSONAL HYGIENE: Of equal importance is advice regarding personal hygiene. (a) Personal cleanliness: The need to bathe every day and to wear clean clothes should be explained. The hair should also be kept clean and tidy. (b) Rest and sleep: 8 hours sleep, and at least 2 hours rest after mid-day meals should be advised. (c) Bowels: Constipation should be avoided by regular intake of green leafy vegetables, fruits and extra fluids. Purgatives like castor oil should be avoided to relieve constipation. (d) Exercise: Light household work is advised, but manual physical labour during late pregnancy may adversely affect the foetus. (e) Smoking: Smoking should be cut down to a minimum. Expectant mothers who smoke heavily produce babies much smaller than the average - it is because nicotine has a vasoconstrictor influence in the uterus and induces a degree of placental insufficiency. The adverse effects of smoking range from low birth-weight to an increased risk of perinatal death of the infant (14). Women who smoke during pregnancy give birth to babies which on an average weigh 170g less at term than the babies of non-smokers. The perinatal mortality amongst babies whose mothers smoked during pregnancy is between 10-40 per cent higher than in non-smokers. (f) Alcohol: Evidence is mounting that alcohol can cause a range of fertility problems in women. Moderate to heavy drinkers who become pregnant have greater risk of pregnancy loss (15), and if they do not abort, their children may have various physical and mental problems (16). Heavy drinking has been associated with a fetal syndrome (FAS) which includes intrauterine growth retardation and developmental delay. More recently, it has been shown that the consumption of even moderate amount of alcohol during pregnancy is associated with an increased risk of spontaneous abortion (17). (g) Dental care: Advice should also be given about oral hygiene. (h) Sexual Intercourse. This should be restricted especially during the last trimester.

(iii) DRUGS: The use of drugs that are not absolutely essential should be discouraged. Certain drugs taken by the mother during pregnancy may affect the foetus adversely and cause foetal malformations. The classical example is thalidomide, a hypnotic drug, which caused deformed hands and feet of the babies born. The drug proved most serious when taken between 4 to 8 weeks of pregnancy. Other examples are LSD which is known to cause chromosomal damage, streptomycin which may cause 8th nerve damage and deafness in the foetus, iodide-containing preparations which may cause congenital goitre in the foetus (18). Corticosteroids may impair foetal growth, sex hormones may produce virilism, tetracyclines may affect the growth of bones and enamel formation of teeth. Anaesthetic agents including pethidine administered during labour can have depressant effect on the baby and delay the onset of effective respiration. Later still in the puerperium, if the mother is breast-feeding, there are certain drugs which are excreted in breast milk. A great deal of caution is required in the drug-intake by pregnant women (19).

(iv) RADIATION: Exposure to radiation is a positive danger to the developing foetus. The most common source of radiation is abdominal X-ray during pregnancy. Case cohort studies have shown that mortality rates from leukaemia and other neoplasms were significantly greater among children exposed to intrauterine X-ray. This is in addition to congenital malformations such as microcephaly. The X-ray examination in pregnancy should be carried out only for definite indications, X-ray dosage kept to minimum. Furthermore, in all women of child-bearing age among whom there is a possibility of pregnancy, elective X-ray should be avoided in the two weeks preceding the menstrual period.

(v) WARNING SIGNS: The mother should be given clear-cut instructions that she should report immediately in case of the following warning signals: (a) swelling of the feet (b) fits (c) headache (d) blurring of the vision (e) bleeding or discharge per vagina, and (f) any other unusual symptoms.

(vi) CHILD CARE: The art of child care has to be learnt. Special classes are held for mothers attending antenatal clinics. Mother-craft education consists of nutrition education, advice on hygiene and childrearing, cooking demonstrations, family planning education, family budgeting, etc.

(3) Specific health protection

(i) ANAEMIA: Surveys in different parts of India indicate that about 50 to 60 per cent of women belonging to low socio-economic groups are anaemic in the last trimester of pregnancy (13). The major aetiological factors being iron and folic acid deficiencies. It is well known that anaemia per se is associated with high incidence of premature births, postpartum haemorrhage, puerperal sepsis and thromboembolic phenomena in the mother. The Government of India has initiated a programme in which 100 mg of elemental iron and 500 mcg of folic acid are being distributed daily for 100 days to pregnant women through antenatal clinics, primary health centres and their subcentres.

(ii) OTHER NUTRITIONAL DEFICIENCIES: The mother should be protected against other nutritional deficiencies that may occur, particularly protein, vitamin and mineral especially vit A and iodine deficiency. In some MCH Centres fresh milk is supplied free of cost to all expectant mothers; where this is not possible, skimmed milk should be given. Capsules of vitamin A and D are also supplied free of cost.

(iii) ASYMPTOMATIC BACTERIURIA (ASB): Urinary tract infection during pregnancy are associated with risks to both mother and foetus. It includes pyelonephritis preterm birth, low birth weight and increased perinatal mortality. Because of physiological changes during pregnancy, the pregnant woman is more prone to urinary tract infection. Midstream urine culture is the recommended method for diagnosis of ASB. If culture facility is not available on-site, midstream urine gram-staining is recommended for the diagnosis (10). The patient should be appropriately treated for ASB.

(iv) GESTATIONAL DIABETES: Hyperglycaemia first detected at any time during pregnancy should be classified as either gestational diabetes mellitus or diabetes mellitus in pregnancy according to WHO criteria. Gestational diabetes is high blood sugar that develops during pregnancy and usually disappears after giving birth. It can occur at any stage of pregnancy but is more common in the second half. Having gestational diabetes also means that the woman is at increased risk of developing type 2 diabetes in the future. At the first antenatal visit, family history of diabetes should be recorded to determine if the woman is more at risk of gestation diabetes (10). The general symptoms are excessive thirst and hunger, frequent urination, drowsiness or fatigue, dry itchy skin, blurring of vision, slow healing of wounds. The second pregnancy may be associated with type 2 diabetes. Hyperglycaemia during pregnancy can harm
(v) **TOXEMIAS OF PREGNANCY** : The presence of albumin in urine and an increase in blood pressure indicates toxemias of pregnancy. Their early detection and management are indicated. Efficient antenatal care minimizes the risk of toxemias of pregnancy.

(vi) **TETANUS** : If the mother was not immunized earlier, 2 doses of adsorbed tetanus toxoid should be given – the first dose at 16–20 weeks and the second dose at 20–24 weeks of pregnancy. The minimum interval between the 2 doses should be one month. No pregnant woman should be denied even one dose of tetanus toxoid, if she is seen late in pregnancy. For a woman who has been immunized earlier, one booster dose will be sufficient. When such a booster has been given, it will provide necessary cover for subsequent pregnancies, during the next 5 years. It is advised not to inject tetanus toxoid at every successive pregnancy because of the risk of hyperimmunization and side-effects.

(vii) **SYPHILIS** : Syphilis is an important preventable cause of pregnancy wastage in some countries. Pregancies in women with primary and secondary syphilis often end in spontaneous abortion, stillbirth, perinatal death, or the birth of a child with congenital syphilis. Syphilitic infection in the pregnant woman is transmissible to the foetus. Neurological damage with mental retardation is one of the most serious consequences of congenital syphilis. When the mother is suffering from syphilis, infection of the foetus does not occur before the 4th month of pregnancy; it is most likely to occur after the 6th month by which time the Langhan's cell layer has completely atrophied (20). Infection of the foetus is most likely to occur when the mother is suffering from primary or secondary stages of syphilis than late syphilis.

It is routine procedure in antenatal clinics to test blood for syphilis at the first visit. Since the mother can subsequently get infected with syphilis, the ideal procedure would be to test blood for syphilis both early and late in pregnancy (20). Congenital syphilis is easily preventable. Ten daily injections of procaine penicillin (600,000 units) are almost always adequate (20).

(viii) **GERMAN MEASLES** : The best estimate of the total risk comes from the long-term prospective study carried out in Great Britain. When rubella was contracted in the first 16 weeks of pregnancy, foetal death or death during the first year of life occurred in the offspring of 17 per cent of the pregnancies. Among survivors who were followed up to age 8 years, 15 per cent had major defects, of which cataract, deafness and congenital heart diseases were the most common. Minor defects were found in an additional 16 per cent. It appears that the risk of all degrees of malformation may remain in the region of 20 per cent up to the 20th week (21).

Ideally we should prevent infection during pregnancy by preventing and controlling the disease in the general population. Currently this is being attempted by vaccination of all school-aged children with rubella vaccine, and including the rubella vaccine in the routine immunization schedule. Supplemeting the community control of infection is the vaccination of all women of childbearing age who are sero-negative. Before vaccinating, it is advisable that pregnancy be ruled out and effective contraception be maintained for 8 weeks after vaccination because of the possible risk to the foetus from the virus.

(ix) **Rh STATUS** : The foetal red cells may enter the maternal circulation in a number of different circumstances, during labour, caesarean section, therapeutic abortion, external cephalic version, and apparently spontaneously in the late pregnancy. The intrusion of these cells, if the mother is Rh-negative and the child is Rh-positive, provokes an immune response in her so that she forms antibodies to Rh which can cross the placenta and produce foetal haemolysis. The same response may be produced to a greater degree by a transfusion of Rh-positive blood. In a pregnant woman, immunization only occurs during labour, so that the child although Rh-positive, is unaffected except where the mother has been already sensitized. In the second or subsequent pregnancies, if the child is Rh-positive, the mother will react to the smallest intrusion of foetal cells by producing antibodies to destroy foetal blood cells causing haemolytic disease in the foetus. Clinically haemolytic disease takes the form of hydrops foetalis, icterus gravis neonatorum (of which kernicterus is often a sequell) and congenital haemolytic anaemia.

It is a routine procedure in antenatal clinics to test blood for Rhesus type in early pregnancy. If the woman is Rh-negative and the husband is Rh-positive, the test should be done under surveillance for determination of Rh-antibody levels during antenatal care. The blood should be further examined at 28 weeks and 34–36 weeks of gestation for antibodies. Rh anti-D immunoglobulin should be given at 28 weeks of gestation so that sensitization during the first pregnancy can be prevented. If the baby is Rh-positive, the Rh anti D immunoglobulin is given again within 72 hours of delivery. It should also be given after abortion. Post maturity should be avoided. Whenever there is evidence of haemolytic process in foetus-in-utero, the mother should be shifted to an equipped centre specialized to deal with Rh problems. The incidence of haemolytic disease due to Rh factor in India is estimated to be approximately one for every 400 to 500 live births.

(x) **HIV INFECTION** : HIV may pass from an infected mother to her foetus, through the placenta or to her infant during delivery or by breast-feeding. About one-third of the children of HIV-positive mothers get infected through this route. The risk of transmission is higher if the mother is newly infected or if she has already developed AIDS. Voluntary prenatal testing for HIV infection should be done as early in pregnancy as possible for pregnant women who are at great risk (if they or their partner has a number of sexual partners; has a sexually transmitted disease; uses illicit injectable drugs etc.). Universal confidential voluntary screening of pregnant women in high-prevalence areas may allow infected women to choose therapeutic abortion, make an informed decision on breast-feeding, or receive appropriate care. Screening should not be used as a substitute for primary prevention through community-wide education on safe sexual practice, making condoms readily available and preventing parenteral transmission (22).

(xi) **HEPATITIS B INFECTION** : Spread of infection from HBV carrier mothers to their babies appears to be a factor for the high prevalence of HBV infection in some regions. The mechanism of perinatal infection is uncertain. Most infections appear to occur at birth. Transmission of the virus to the baby after delivery is likely if both surface antigen and e antigen are positive. Vertical transmission can be blocked by immediate post-delivery administration of B immunoglobulin and hepatitis B vaccine. Please refer to page 236 for details.
severe defects are detected. Typical examples are screening for chromosomal abnormalities associated with serious birth defects, screening for direct evidence of congenital structural anomalies, and screening for haemoglobinopathies and other inherited conditions detectable by biochemical assay. Universal screening for direct evidence of congenital structural anomalies is performed in pregnancy in order to make the option of therapeutic abortion available when severe defects are detected. Typical examples are screening for trisomy 21 (Down's syndrome) and severe neural tube defects. Women aged 35 years and above, and those who already have an afflicted child are at higher risk.

(4) Mental preparation
Antenatal care does not mean only palpation, blood and urine examination and pelvic measurements. These are no doubt important aspects of antenatal care. Mental preparation is as important as physical or material preparation. Sufficient time and opportunity must be given to the expectant mothers to have a free and frank talk on all aspects of pregnancy and delivery. This will go a long way in removing her fears about confinement. The "mothercraft" classes at the MCH Centres help a great deal in achieving this objective.

(5) Family planning
Family planning is related to every phase of the maternity cycle. The mother is psychologically more receptive to advice on family planning than at other times. Educational and motivational efforts must be initiated during the antenatal period. If the mother has had 2 or more children, she should be motivated for puerperal sterilization. In this connection, the All India Postpartum Programme services are available to all expectant mothers in India (23).

(6) Paediatric component
It is suggested that a paediatrician should be in attendance at all antenatal clinics to pay attention to the under-fives accompanying the mothers.

INTRANATAL CARE

Childbirth is a normal physiological process, but complications may arise. Septicaemia may result from unsterilized instruments and tetanus neonatorum from the use of unsterilized instruments. The need for effective intranatal care is therefore indispensable, even if the delivery is going to be a normal one. The emphasis is on the cleanliness. It entails - clean hands and fingernails, a clean surface for delivery, clean cord care i.e., clean blade for cutting the cord and clean tie for the cord, no application on cord stump, and keeping birth canal clean by avoiding harmful practices. Hospitals and health centres should be equipped for delivery with midwifery kits, a regular supply of sterile gloves and drapes, towels, cleaning materials, soap and antiseptic solution, as well as equipment for sterilizing instruments and supplies. There are delivery kits available with the items needed for basic hygiene for delivery at home, where a midwife with a midwifery kit is not likely to be present. The aims of good intranatal care are:

(i) thorough asepsis;
(ii) delivery with minimum injury to the infant and mother;
(iii) readiness to deal with complications such as prolonged labour, antepartum haemorrhage, convulsions, malpresentations, prolapse of the cord, etc.; and
(iv) Care of the baby at delivery - resuscitation, care of the cord, care of the eyes, etc.

Domiciliary care
Mothers with normal obstetric history may be advised to have their confinement in their own homes, provided the home conditions are satisfactory. In such cases, the delivery may be conducted by the Health Worker Female or trained dai. This is known as "domiciliary midwifery service."

The advantages of the domiciliary midwifery service are:
(1) the mother delivers in the familiar surroundings of her home and this may tend to remove the fear associated with delivery in a hospital; (2) the chances for cross infection are generally lower at home than in the nursery/hospital; and (3) the mother is able to keep an eye upon her children and domestic affairs; this may tend to ease her mental tension.

Domiciliary midwifery is also not without disadvantages:
(1) the mother may have less medical and nursing supervision than in the hospital, (2) she may have less rest; (3) she may be able to resume her domestic duties too soon; and (4) her diet may be neglected. Strictly speaking, many homes in India are unsuitable for even a normal delivery. The argument that childbirth is a natural event and should take place at home does not guarantee that everything will be normal.

Since 72.2 per cent of India's population live in rural areas, most deliveries will have to take place in the home with the aid of Female Health Workers or trained das. Domiciliary out-reach is a major component of intranatal health care. The Female Health Worker, who is a pivot of domiciliary care, should be adequately trained to recognize the "danger signals" during labour and seek immediate help in transferring the mother to the nearest Primary Health Centre or Hospital. The danger signals are:

(1) sluggish pains or no pains after rupture of membranes;
(2) good pains for an hour after rupture of membranes, but no progress;
(3) prolapase of the cord or hand;
(4) meconium-stained liquor or a slow irregular or excessively fast foetal heart;
(5) excessive 'show' or bleeding during labour;
(6) collapse during labour;
(7) a placenta not separated within half an hour after delivery;
(8) post-partum haemorrhage or collapse; and
(9) a temperature of 38.5 deg C or over during labour. There should be a close liaison between domiciliary and institutional delivery services.

Institutional care
About one per cent of deliveries tend to be abnormal, and four per cent "difficult", requiring the services of a doctor. Institutional care is recommended for all "high-risk" cases, and where home conditions are unsuitable.

The mother is allowed to rest in bed on the first day after delivery. From the next day, she is allowed to be up and about. The current practice is to discharge the woman after 48 hours lying-in period after a normal delivery.

Rooming-in
Keeping the baby's crib by the side of the mother's bed is called "rooming-in". This arrangement gives an opportunity
for the mother to know her baby. Mothers interested in breast feeding usually find there is a better chance for success with rooming-in. Rooming-in also allays the fear in the mother's mind that the baby is not misplaced in the central nursery. It also builds up her self-confidence.

**POSTNATAL CARE**

Care of the mother (and the newborn) after delivery is known as postnatal or postpartal care. Broadly this care falls into two areas: care of the mother which is primarily the responsibility of the obstetrician; and care of the newborn, which is the combined responsibility of the obstetrician and paediatrician. This combined area of responsibility is also known as perinatology.

**Care of the mother**

The objectives of postnatal care are:

1. To prevent complications of the postnatal period.
2. To provide care for the rapid restoration of the mother to optimum health.
3. To check adequacy of breast-feeding.
4. To provide family planning services; and
5. To provide basic health education to mother family.

**Complications of the postnatal period**

Certain complications may arise during the postpartal period which should be recognized early and dealt with promptly. These are (1) Puerperal sepsis: This is infection of the genital tract within 3 weeks after delivery. This is accompanied by rise in temperature and pulse rate, foul-smelling lochia, pain and tenderness in lower abdomen, etc. Puerperal sepsis can be prevented by attention to asepsis, before and after delivery. This is particularly important in domiciliary midwifery service. (2) Thrombophlebitis: This is an infection of the veins of the legs, frequently associated with varicose veins. The leg may become tender, pale and swollen. (3) Secondary haemorrhage: Bleeding from vagina anytime from 6 hours after delivery to the end of the puerperium (6 weeks) is called secondary haemorrhage, and may be due to retained placenta or membranes. (4) Others: Urinary tract infection and mastitis, etc. It is extremely important to look for these complications in the postpartal period and prevent or treat them promptly.

**Restoration of mother to optimum health**

The second objective of postnatal care is to provide care whereby, the woman can recuperate physically and emotionally from her experience of delivery. The broad areas of this care fall into three divisions:

**PHYSICAL**

(1) Postnatal examinations: Soon after delivery, the health check-ups must be frequent, i.e., twice a day during the first 3 days, and subsequently once a day till the umbilical cord drops off. At each of these examinations, the FHW checks temperature, pulse and respiration, examines the breasts, checks progress of normal involution of uterus, examines lochial, for any abnormality, checks urethra and bowels and advises on perineal toilet, including care of the stiches, if any. The immediate postnatal complications, viz. puerperal sepsis, thrombophlebitis, secondary haemorrhage should be kept in mind. At the end of 6 weeks, an examination is necessary to check-up involution of uterus which should be complete by then. Further visits should be done once a month during the first 6 months, and thereafter once in 2 or 3 months till the end of one year. In rural areas only limited postnatal care is possible. Efforts should be made by the FHWs to give at least 3 to 6 postnatal visits. The common conditions found on examination during the late postnatal period are subinvolution of uterus, retroverted uterus, prolapse of uterus and cervicitis. Postnatal examination offers an opportunity to detect and correct these defects.

(2) Anaemia: Routine haemoglobin examination should be done during postnatal visits, and when anaemia is discovered, it should be treated. In some cases, it may be necessary to continue treatment for a year or more.

(3) Nutrition: Though a malnourished mother is able to secrete as much breast milk as a well nourished one, she does it at the cost of her own health. The nutritional needs of the mother must be adequately met. Often the family budget is limited; the mother should be shown the means how she can eat better with less money.

(4) Postnatal exercises: Postnatal exercises are necessary to bring the stretched abdominal and pelvic muscles back to normal as quickly as possible. Gradual resumption of normal household duties may be enough to restore one's figure.

**PSYCHOLOGICAL**

The next big area of postnatal care involves a consideration of the psychological factors peculiar to the recently delivered woman. One of the psychological problems is fear which is generally borne of ignorance. Other problems are timidity and insecurity regarding the baby. If a woman is to endure cheerfully the emotional stresses of childbirth, she requires the support and companionship of her husband. Fear and insecurity may be eliminated by proper prenatal instruction. The so called postpartum psychosis is perhaps precipitated by birth; and it is rather uncommon.

**SOCIAL**

It has been said that the most important thing a woman can do is to have a baby. This is only part of the truth. The really important thing is to nurture and raise the child in a wholesome family atmosphere. She, with her husband, must develop her own methods.

**Breast-feeding**

Postnatal care offers an excellent opportunity to find out how the mother is getting along with her baby, particularly with regard to feeding. For many children, breast milk provides the main source of nourishment in the first year of life. In some societies, lactation continues to make an important contribution to the child's nutrition for 18 months or longer. In the world's more affluent societies, breast-feeding appears to have become a lost art and the feeding bottle has usurped the breast. When the standard of environmental sanitation is poor and education low, the content of the feeding bottle is likely to be as nutritionally poor as it is bacteriologically dangerous. It is therefore very important to advise the mothers to avoid the feeding bottle.

A great asset in India is that an average Indian mother, although poor in nutritional status, has a remarkable ability to breast-feed her infant for prolonged periods, sometimes extending to nearly 2 years and beyond. Longitudinal and cross-sectional studies indicate that poor Indian women secrete as much as 400 to 600 ml of milk per day during the first year (Table 2). No other food is required to be given until 6 months after birth. At the age of 6 months, breast milk should be supplemented by additional foods rich in protein and other nutrients (e.g., animal milk, soft-cooked mashed vegetables, etc.). These are called supplementary foods which should be introduced very gradually in small amounts.
Family planning

It has already been stressed that family planning is related to every phase of maternity cycle. Every attempt should be made to motivate mothers when they attend postnatal clinics or during postnatal contacts to adopt a suitable method for spacing the next birth or for limiting the family size as the case may be. Postpartum sterilization is generally recommended on the 2nd day after delivery. Although lactation confers some protection against conception, it cannot be depended upon; contraceptives have to be supplied immediately postpartum. To ask the mother to come at the time of her first menstruation may be too late. A contraceptive must therefore be used, that will not affect lactation in the early postpartum period. In this connection, IUD and conventional (non-hormonal) contraceptives are the choices during the first 6 months following delivery. In general, combined or sequential oral “pills” should be avoided in a lactating mother as they do suppress lactation. Fortunately, evidence is accumulating that progestogens alone have little or no effect on lactation. The injection of medroxy-progesterone acetate (MPA) after delivery has been found to be successful in ensuring spacing of pregnancy without suppressing lactation; however, because of its side-effects (e.g., irregular uterine bleeding, prolonged infertility) some countries have limited its use to multiparae at ages 35 and over, or who have already completed their families. MPA is not recommended for general use.

Basic health education

Health education during the postnatal period should cover the following broad areas: (a) hygiene – personal and environmental; (b) feeding for mother and infant; (c) pregnancy spacing; (d) importance of health check-up; and (e) birth registration.

CARE OF CHILDREN

This section focuses on children in the age group 0-14 years. This is the most important age group in all societies, not because they constitute about 40 per cent of the total population, but because there is a renewed awareness that the determinants of chronic disease in later life and health behaviour are laid down at this stage (24). Family influences and education are of the highest importance, and these experiences ultimately influence patterns of their future lifestyles, occupational skills, and even political attitudes and leadership. The childhood period is also a vital period because of the so-called socialization process, that is, transmission of attitudes, customs and behaviour. In addition, of course, they are vulnerable to disease, death and disability owing to their age, sex, place of living, socio-economic class and a host of other variables. Certain specific biological and psychological needs must be met to ensure the survival and healthy development of the child and future adult.

It is customary to divide the childhood into the following age-periods:

1. Infancy (up to 1 year of age):
   a. Neonatal period (first 28 days of life).
   b. Post neonatal period (28th day to 1 year).
2. Pre-school age (1-4 years).
3. School age (5-14 years).

Antenatal paediatrics

Fifty years ago, the main purpose of antenatal care was the prevention of maternal mortality. With the fall in the maternal mortality, to about 0.2 per 1000 live births, attention has shifted to the child — first to decrease perinatal mortality, secondly to prevent perinatal morbidity; and more recently to the “foetus at risk”. This has given rise to the concept of antenatal paediatrics. Recent technical developments such as amniocentesis, ultrasonography, fetoscopic and chorionic biopsy have contributed significantly to the diagnosis of congenital abnormalities and inborn errors of metabolism (25, 26). This knowledge has led to the recognition that causation and possible prevention may lie in intra-uterine life. The emphasis has greatly changed in the care of the child with the prevention of disorders (e.g., low birth weight, foetal disorders and neonatal asphyxia) assuming greater importance.

Antenatal care should, appropriately, begin even before the mother conceives and enters the maternity cycle; this care comprising such measures as genetic counselling for prospective parents; limitation and proper spacing of births with intervals of 2-3 years; delaying a young woman’s first pregnancy until she is physically and socially mature enough to cope with it; ensuring adequate maternal nutrition; protection of the unborn against intrauterine infections and other adverse influences. In a developing country such as India, all this may not be possible, but certainly some elements, such as improvement of maternal nutrition, family planning and counselling could go a long way in ensuring maternal and foetal health.

INFANCY

Infants (0-1 year) constitute about 2.92 per cent of the total population in India. Of the 136 million children born each year in the world, 90 per cent are in the third world. Although the chances of survival of these newborns has improved by 50 per cent in the last 20 years, the first few hours, days and months of their lives are still an obstacle race. From the time of birth, 20-30 per cent of babies are under-weight. That makes them vulnerable to infection and disease. About 40 per cent of total infant mortality occurs in the first month of life. Then comes the weaning period, when one out of four surviving children receives neither the quality nor the quantity of food needed to replace the substances provided by mother’s milk. The result is that more and more children in developing countries reach adulthood with their health already largely impaired. An infant mortality rate of
58 per thousand, as compared to 5 per thousand in the developed countries, places India in the unenviable position of being among the less developed in the world. Many low-cost measures are available for saving life of millions of children, like immunization, breast feeding, birth spacing, growth monitoring, improved weaning, oral rehydration. Attention is focused on these elements of child health care in developing countries.

NEONATAL CARE

A flow chart of the optimum care of the newborn is as shown in Fig. 2. This aspect of family health services has been termed neonatology. This branch of medicine is, perhaps, more than any other, dependent on teamwork in which disciplines of obstetrics and gynaecology, paediatrics, preventive and social medicine, community health services and nursing have an important part to play, if any impact is to be made on the vast problems of perinatal and neonatal mortality and morbidity. The paediatrician has a key role as a coordinator and guide for the whole team.

Early neonatal care

The first week of life is the most crucial period in the life of an infant. In India, 61.3 per cent of all infant deaths occur within the first month of life. Of these, more than half may die during the first week of birth. This is because the newborn has to adapt itself rapidly and successfully to an alien external environment. The risk of death is the greatest during the first 24-48 hours after birth. The problem is more acute in rural areas where expert obstetric care is scarce, and the home environmental conditions in which the baby is born, are usually unsatisfactory.

The objective of early neonatal care is to assist the newborn in the process of adoption to an alien environment, which involves:

(i) establishment and maintenance of cardio-respiratory functions;
(ii) maintenance of body temperature;
(iii) avoidance of infection;
(iv) establishment of satisfactory feeding regimen; and
(v) early detection and treatment of congenital and acquired disorders, especially infections.

Congenital infections caused by toxoplasmosis, rubella, human (alpha) herpes-virus 1 or 2, human (beta) herpes virus, and syphilis (TORCHES synonyms) is associated with high mortality rate in the neonates (27).

Immediate care

1. CLEARING THE AIRWAY

Establishment and maintenance of cardio-respiratory functions (e.g., breathing) is the most important thing the moment the baby is born, and everything else is secondary. To help establish breathing, the airways should be cleared of mucus and other secretions. Positioning the baby with his head low may help in the drainage of secretions. This process can be assisted by gentle suction to remove mucus and amniotic fluid. Resuscitation becomes necessary if natural breathing fails to establish within a minute, as in the case of babies who have already been subject to hypoxia during labour. In these cases, resuscitation may require more active measures such as suction, application of oxygen mask, intubation and assisted respiration. All labour wards should be equipped with resuscitation equipment including oxygen. If the heart has stopped beating for 5 minutes, the baby is probably dead.

2. APGAR SCORE

The Apgar score is taken at 1 minute and again at 5 minutes after birth. Today it is considered as negligence to omit Apgar scoring of a newborn infant, especially low birth weight babies (28). It requires immediate and careful observation of the heart rate, respiration, muscle tone, reflex response and colour of the infant. Each sign is given a score of 0, 1 or 2 (Table 3). It provides an immediate estimate of the physical condition of the baby. A perfect score should be 9 or 10; 0-3 indicates that the baby is severely depressed and 4-6 moderately depressed. A score below 5 needs prompt action. Infants with low Apgar scores at 5 minutes of age are subject to a high-risk of complications and death during the neonatal period (28).
3. CARE OF THE CORD

In the case of the normal infant, the umbilical cord should be cut and tied when it has stopped pulsating. The advantage is that the baby derives about 10 ml of extra blood, if the cord is cut after pulsation ceases. This is particularly important in India, where anaemia is frequent. Care must be taken to prevent tetanus of the newborn by using properly sterilized instruments and cord ties. It is essential to apply an antiseptic preparation on the cord stump and the skin around the base. The cord should be kept as dry as possible. It dries and shrivels up and separates from inner to outer side. Instil a drop of freshly prepared silver nitrate solution (1 per cent) to prevent gonococcal infection should be cleaned with sterile wet swabs, one for each eye.

4. CARE OF THE EYES

Before the eyes are open, the lid margins of the newborn are kept away from cold walls, open windows and from draught (30). A newborn baby is wet from amniotic fluid and can easily become cold. Drying the baby with clean cloth to remove vernix, meconium and blood clots is done by the nursing staff. The baby is then wrapped in dry, clean cloth from head to foot to prevent heat loss. First bath is given after temperature stabilization, preferably after a week.

5. CARE OF THE SKIN

A newborn baby is wet from amniotic fluid and can easily become cold. Drying the baby with clean cloth to remove vernix, meconium and blood clots is done by the nursing staff. The baby is then wrapped in dry, clean cloth from head to foot to prevent heat loss. First bath is given after temperature stabilization, preferably after a week.

6. MAINTENANCE OF BODY TEMPERATURE

The normal body temperature of a newborn is between 36.5 to 37.5°C. A newborn baby is projected out of warm womb of the mother into an environment which may be 10 to 20°C cooler especially in winter months in India. A newborn has little thermal control and can lose body heat quickly. Immediately after birth; most of the heat loss occurs through evaporation of the amniotic fluid from the body of the wet child. As much as 75 per cent of the heat loss can occur from the head. It is important that immediately after birth the child is quickly dried with a clean cloth and wrapped in warm cloth and given to the mother for skin-to-skin contact and breast-feeding. Practices such as separating the baby from the mother for the first 12-24 hours of life are harmful. Pre-term and low birth weight babies lose heat more easily through their thin skin as they have less sub-cutaneous fat for insulation. Putting the newborn on a cold surface such as metallic tray, rubber sheeting or weighing scale should be avoided, and the child should be kept away from cold walls, open windows and from draught (30).

7. BREAST-FEEDING

Breast-feeding should be initiated within an hour of birth instead of waiting several hours as is often customary. Although there is little milk at that time, it helps to establish feeding and a close mother–child relationship, known as “bonding”.

The first milk which is called “colostrum” is the most suitable food for the baby during this early period because it contains a high concentration of protein and other nutrients the body needs; it is also rich in anti-infective factors which protect the baby against respiratory infections and diarrhoeal diseases. Supplementary feeds are not necessary. The regular milk comes on the third to sixth day after birth. The baby should be allowed to breast-feed whenever it wants. Feeding the baby on demand helps the baby to gain weight. It is very important to advise mother to avoid feeding bottles.

Neonatal examinations

a. FIRST EXAMINATION

The first examination is made soon after birth, and preferably in the delivery room. This examination is (a) to ascertain that the baby has not suffered injuries during the birth process; (b) to detect malformations especially those requiring urgent treatment; and (c) to assess maturity.

The following abnormalities found on examination should be immediately attended to: (a) cyanosis of the lips and skin; (b) any difficulty in breathing; (c) imperforated anus; (d) persistent vomiting; (e) signs of cerebral irritation such as twitches, convulsions, neck rigidity, bulging of anterior fontanel, and (g) temperature instability.

b. SECOND EXAMINATION

The second examination should be made preferably by a paediatrician within 24 hours after birth. This examination should form the first stage of a continual process of health care surveillance. It is a detailed systematic examination from head to foot, conducted in good light. The following protocol will be found useful for such an examination (31).

1. Body size.
   - Body weight; crown–heel length; head and thoracic perimeters.

2. Body temperature.
3. Skin:
   - Observe for cyanosis of lips and skin; jaundice; pallor; generalized erythema; vesicular and bullous lesions
4. Cardio-respiratory activities:
   - Cardiac murmurs; absence of femoral pulse; central cyanosis, a respiratory rate of over 60 per minute; thoracic cage retraction on inspiration.
5. Neuro–behavioural activity:
   - (i) Posture: neck retraction; frog-like posture; hyper-extension of all limbs; hyperflexion of all limbs; asymmetrical posture
   - (ii) Muscle tone: tendon reflexes; cry; movements
6. Head and face:
   - Hydrocephalus; large fontanelles; prominent scalp vein
   - (i) Eyes: cataract; coloboma; conjunctivitis
   - (ii) Ears: dysmorphism; accessory auricles; preauricular pits
   - (iii) Mouth and lips: Hare lip; cleft palate.
7. Abdomen:
   - Signs of distension; abnormal masses; imperforate anus
8. Limbs and joints:
   - Deformities of joints; congenital dislocation of the hips; extra digits.
9. Spine:
   - Neural tube defects
10. External genitalia:
    - Male: Hypospadias; undescended testis; hydrocele
    - Female: fused labia; enlarged clitoris.

The infected newborn (30)

Neonatal infection is particularly frequent in Africa. It is the main cause of neonatal mortality in many developing countries. Contributing factors are related to the environment (traditional practices, poor hygiene), the course of pregnancy (premature rupture of membranes) and constitutional fragility (prematurity, small-for-date, dysmaturity). Transplacental contamination is one of the important causes of infection in newborns. Early detection of newborns at high risk of transplacental infection is important, so that close monitoring and preventive action may be implemented.

NEONATAL TETANUS: It can be prevented by vaccination of pregnant women and sero-vaccination of newborns in case of at-risk delivery. These measures have proved effective in those countries where they are systematically applied.

CONGENITAL SYPHILIS: The frequency of congenital syphilis is on rise in some large African cities. Diagnosis is essentially based on the evidence of syphilis in the mother, since clinical signs of congenital syphilis often do not occur at once. In case of doubt, and if there is risk of inadequate subsequent medical surveillance of the baby, treatment with 2.4 to 4.8 million U of Benzathine Penicillin may be recommended.

NEWBORN WITH AN HBV-POSITIVE MOTHER: Chronic carriers of hepatitis virus are extremely frequent in some countries. Babies may be infected at birth when the mother is a carrier of this virus. The risk of transmission is somewhere around 20 per cent when the mother has the HBs antigen only, and around 90 per cent when she also has the HBe antigen. Transmission occurs through the blood and the genital secretions and therefore affects the newborn during the immediate perinatal period and throughout infancy. It is not a contraindication of breast-feeding.

If the newborn is infected, there is a risk that he/she will become a chronic carrier, and tend to develop active chronic hepatitis, cirrhosis or primary cancer of liver during adulthood. 50 per cent of severe cases of infantile hepatitis before age one year are the outcome of untreated perinatal transmission.

It is possible to prevent perinatal transmission by sero-prophylaxis combined with vaccination – an intramuscular injection of 0.5 ml of hepatitis B immunoglobulin along with hepatitis B vaccine within 24 hours of birth. The vaccine must be repeated at 6, 10 and 14 weeks of age.

This prophylaxis has proved effective. The real problem is to detect mothers who are chronic carriers of the HBs antigen, and the high cost of prevention.

NEWBORN WITH AN HIV-POSITIVE MOTHER: The rapidity of the propagation of HIV infection is a source of great concern. About 30 per cent babies born to HIV-positive mothers get infected. Transmission of infection mostly occurs at the end of the pregnancy, and it is not influenced by the type of delivery. The virus has been isolated in breast-milk. Although there is probably a risk of transmission of infection through breast-milk, prohibiting breast-feeding is debatable, as it is so essential for the survival of newborn in developing countries. The risk of transmission depends on the severity of the mother's case. It is higher from mothers with AIDS, but may also occur from seropositive cases. The infection can be prevented by giving ART. Please refer to page 370 for details. The question of whether to perform BCG vaccination arises – it is contraindicated in infected children, and therefore, should not be performed in the offspring of HIV positive mothers until it is determined whether the baby is infected or not. This is only feasible at the end of several months when the maternal antibodies are completely eliminated (30).

MEASURING THE BABY

Measurements of birth-weight, length (height) and head circumference are the simplest and one of the reliable means by which the health and maturity of a baby is evaluated.

1. Birth-weight

The birth-weight should be taken preferably within the first hour of life, before significant post-natal weight loss has occurred (32). The naked baby should be placed on a clean towel on the scale pan. In home delivery, weight is taken by placing the baby in a sling bag using a salter weighing scale. The child is weighed to the nearest 100 g according to the standard method for weight measurement.

The average birth-weight of infants is lower in many developing countries than it is in developed countries. There are reasons to believe that this difference is not of genetic origin but is due largely to maternal malnutrition.

2. Length (height)

This need not be taken immediately if the baby's condition gives rise to anxiety, but should be recorded within the first 3 days. Length can be taken most accurately with a measuring board (infantometer) with a fixed head piece on which the infant lies supine with its legs fully extended and the feet flexed at right angles to the lower legs. Two people are needed to hold the baby correctly. The sliding board is moved firmly against the feet before the reading is taken. Length is taken to the nearest 0.1 cm.
3. Head circumference

This measurement may change slightly during the first 3 days owing to moulding during labour. It is taken with a tape measure at the maximum circumference of the head in the occipito-frontal diameter.

The purpose of taking these measurements are:

(i) to assess the baby's size against known standards for the population;
(ii) to compare the size with estimated period of gestation; and
(iii) to provide a baseline against which subsequent progress can be measured.

Anthropometric measurements may be classified as:

(a) Weight: kg
(b) Length: total height, sitting height, heel knee-length
(c) Perimeters: head, chest, abdomen, arm, calf
(d) Diameters: biacromial, bicristal, biceps, bicipital, bicondylar, bistyloid, bicoccygeal, biepicondylar
(e) Skinfold thickness: triceps, biceps, subscapular.

NEONATAL SCREENING

The object of screening newborns is primarily to detect infants with treatable genetic, developmental and other abnormalities, and secondarily, to provide their parents with genetic counselling. The Apgar score and routine clinical examinations are simple screening tests which should be carried out on all newborn infants. 10 to 15 ml of cord blood should be collected at birth and saved in the refrigerator for 10,000-20,000 births) disorder of amino acid metabolism.

(a) Phenylketonuria (PKU): PKU is a rare (incidence 1 in 10,000-20,000 births) disorder of amino acid metabolism. This is an autosomal recessive trait in babies who are homozygous with a deficiency in the enzyme phenylalanine hydroxylase (PAH) which normally converts phenylalanine to tyrosin. The deficiency results in raised serum phenylalanine concentrations causing mental retardation and tendency to seizures if the child does not receive low phenylalanine diet. Mass screening of blood phenylalanine in neonates is performed in many countries by the Guthrie test. It is possible to test for all three types of metabolic error, namely PKU, galactosaemia and maple syrup urine disease by taking blood from the 6-10 days old baby by heel prick and collecting 3 or 4 separate drops of it on thick absorbent filter paper. The treatment of PKU consists of a diet free of phenylalanine. Careful dietary management in affected children results in normal physical and mental development.

(b) Neonatal hypothyroidism: This is the most common disorder that is screened. Congenital hypothyroidism leads to serious sequelae, including severe mental retardation, which can be prevented if medical treatment is given within the first 1-2 months of life. The test involves measuring the radio-immuno-assays of the thyroid hormone T4 or the thyroid-stimulating hormone (TSH). By examining the cord blood of newborns, potential victims of IDD could be identified and proper prevention can be taken at such an early stage of life.

3. Identification of “at-risk” infants

The number of infants (and children 1-5 years of age) in a community, or attending a child health clinic, may be so large that it may not be possible to give sufficient time and attention to all of them. It is therefore necessary to identify particularly those “at-risk” and give them special intensive care, because it is these “at-risk” babies that contribute so largely to perinatal, neonatal and infant mortality. The basic criteria for identifying these babies include:

1. birth weight less than 2.5 kg;
2. twins;
3. birth order 5 and more;
4. artificial feeding;
5. weight below 70 per cent of the expected weight (i.e., II and III degrees of malnutrition);
6. failure to gain weight during three successive months;
7. children with PEM, diarrhoea; and
8. working mother/one parent.

Late neonatal care

The remaining three weeks of the neonatal period carry the common and serious hazards of infection and failure of satisfactory nutrition. Diarrhoea and pneumonia take a heavy toll of life in infants exposed to an unsatisfactory environment. The case fatality rate of what would normally be trivial episodes can increase dramatically when elementary care is not given.

LOW BIRTH WEIGHT

The birth weight of an infant is the single most important determinant of its chances of survival, healthy growth and development.

There are two main groups of low birth weight babies –
(a) those born prematurely (short gestation); and
(b) those with foetal growth retardation. In countries where the population of low birth weight infants is less, short gestation period is the major cause. In countries where the proportion is high (e.g. India), the majority of cases can be attributed to foetal growth retardation.

By international agreement low birth weight has been defined as a birth weight of less than 2.5 kg (upto and
and environmental factors, but the cause of spontaneous preterm labor remains unidentified in up to half of all cases, varying by gestational age, social economic status, short maternal stature, very young age, maternal violence, and performance.

PRETERM BABIES (11)

Preterm is defined as babies born alive before 37 weeks of pregnancy are completed. There are sub-categories of preterm birth, based on gestational age:

a. **Preterm**: Babies born before the end of 37 weeks gestation (less than 259 days).
b. **Term**: Babies born from 37 completed weeks to less than 42 completed weeks (259 to 293 days) of gestation.
c. **Postterm**: Babies born at 42 completed weeks or any time thereafter (294 days and over) of gestation.

A LBW infant then, is any infant with a birth weight of less than 2.5 kg regardless of gestational age. It includes two kinds of infants:

**PREVENTIVE MEDICINE IN OBSTETRICS, PAEDIATRICS AND GERIATRICS**

More than 1 in 10 of the world’s babies born in 2010 were born prematurely, making an estimated 15 million preterm births (defined as before 37 weeks of gestation) of which more than 1 million died as a result of their prematurity. Prematurity is now the second-leading cause of death in children under 5 years, and the single most important cause of death in the critical first month of life. For the babies who survive, many face a lifetime of significant disability.

INCIDENCE

More than 1 in 10 of the world’s babies born in 2010 were born prematurely, making an estimated 15 million preterm births (defined as before 37 weeks of gestation) of which more than 1 million died as a result of their prematurity. Prematurity is now the second-leading cause of death in children under 5 years, and the single most important cause of death in the critical first month of life. For the babies who survive, many face a lifetime of significant disability.

Causes of preterm births (11)

Preterm birth is a syndrome with a variety of causes which can be classified into two broad subtypes: (1) spontaneous preterm birth (spontaneous onset of labor or following prelabor premature rupture of membranes (pPROM) and (2) provider-initiated preterm birth (defined as induction of labor or elective caesarean birth before 37 completed weeks of gestation for maternal or fetal indications (both “urgent” or “discretionary”), or other non-medical reasons.

Spontaneous preterm birth is a multi-factorial process, resulting from the interplay of factors causing the uterus to change from quiescence to active contractions and to birth before 37 completed weeks of gestation. The precursors to spontaneous preterm birth vary by gestational age, social and environmental factors, but the cause of spontaneous preterm labor remains unidentified in up to half of all cases. Maternal history of preterm birth is a strong risk factor and most likely driven by the interaction of genetic, epigenetic and environmental risk factors.

Elevated risk of preterm birth also demands increased attention to maternal health, including the antenatal diagnosis and management of NCDs and other conditions known to increase the risk of preterm birth. Premature babies, in turn, are at greater risk of developing NCDs, like hypertension and diabetes, and other significant health conditions later in life, creating an intergenerational cycle of risk. The link between prematurity and an increased risk of NCDs takes on an added public health importance when considering the reported increase in the rates of both worldwide. Table 4 summarizes the types of preterm births and the risk factors involved.

**SMALL-FOR-DATE (SFD) BABIES**:

These may be born at term or preterm. They weigh less than the 10th percentile for the gestational age. These babies are clearly the result of retarded intrauterine growth.

Computation

The percentage of LBW babies is computed as:

\[
\text{Percentage of LBW babies} = \frac{\text{Live-born babies with birth weight less than 2.5 Kg}}{\text{Total number of live births}} \times 100
\]

The factors associated with intrauterine growth retardation are multiple and interrelated to mother, the placenta or to the foetus. The maternal factors include malnutrition, severe anaemia, heavy physical work during pregnancy, hypertension, malaria, toxoaemia, smoking, low economic status, short maternal stature, very young age,
high parity and close birth spacing, low education status etc. (34). The placental causes include placental insufficiency and placental abnormalities. The foetal causes include foetal abnormalities, intrauterine infections, chromosomal abnormality and multiple gestation.

SFD babies have a high risk of dying not only during the neonatal period but during their infancy, thus significantly raising the rate of infant and perinatal mortality and contribute greatly to immediate and long term health problems. Most of them become victims of protein-energy malnutrition and infections.

In the developing countries, adverse prenatal and postnatal development of the child is associated with 3 interrelated conditions: malnutrition, infection and unregulated fertility which are often due to poor socio-economic and environmental conditions.

**IMPORTANCE**

LBW is one of the most serious challenges in maternal and child health in both developed and developing countries. Its public health significance may be ascribed to numerous factors – its high incidence; its association with mental retardation and a high risk of perinatal and infant mortality and morbidity (half of all perinatal and one-third of all infant deaths are due to LBW); human wastage and suffering; the very high cost of special care and intensive care units and its association with socio-economic underdevelopment (35).

LBW is the single most important factor determining the survival chances of the child. Many of them die during their first year. The infant mortality rate is about 20 times greater for all LBW babies than for other babies. The lower the birth weight, the lower is the survival chance. Many of them become victims of protein-energy malnutrition and infection. LBW is thus an important guide to the level of care needed by individual babies. LBW also reflects inadequate nutrition and ill-health of the mother. There is a strong and significant positive correlation between maternal nutritional status and the length of pregnancy and birth weight. A high percentage of LBW therefore points to deficient health status of pregnant women, inadequate prenatal care and the need for improved care of the newborn.

**PREVENTION**

Experts opine that the rates of LBW babies could be reduced to not more than 10 per cent in all parts of the world (36). It is clear from the multiplicity of causes that there is no universal solution. Interventions have to be cause-specific. Main attention has been given in recent years to ways and means of preventing LBW through good prenatal care and intervention programmes, rather than “treatment” of LBW babies born later.

**DIRECT INTERVENTION MEASURES**

The incidence of LBW can be reduced if pregnant women “at risk” are identified and steps are taken to reduce the risk. For this approach the women need to be identified early in pregnancy. To achieve this goal, the mothers health card – which is simple and can be used by primary health care worker – has been found very useful. The risk factors are: mother’s malnutrition, heavy work load, diseases and infections and high blood pressure. Added to malnutrition, too many and too frequent pregnancies contribute to the continued depletion of her body. Both malnutrition and morbidity due to infections during pregnancy are amenable to correction or can be prevented. Some of the direct interventions are as follows:

(i) **Increasing food intake**: Studies have shown that even a relatively small dietary improvement in the malnourished pregnant mother, even during the last trimester, can result in a significant improvement in the birth weight of an infant. In Southern India, treatment of anaemic mothers led to an increase in birth weight of offspring. Direct intervention covers a wide range of activities, viz supplementary feeding, distribution of iron and folic acid tablets, fortification and enrichment of foods, etc.; (ii) **Controlling infections**: Many maternal infections go unrecognized. They should be diagnosed and treated (e.g., malaria, urinary tract infection, infections due to cryptomegalovirus, toxoplasmosis, rubella and syphilitic infection) or otherwise prevented. These infections can affect foetal growth in several ways; and (iii) **Early detection and treatment of medical disorders**: These include hypertension, toxemias, and diabetes.

**INDIRECT INTERVENTION**

Family planning, avoidance of excessive smoking, improved sanitation measures, and measures aimed at improving the health and nutrition of young girls, each have a role to play. These measures can be expected to be more effective and to have lasting effects only if, at the same time, there are improvements in the socio-economic and environmental conditions and in the distribution of health and social services especially in the under-served areas. Government support could be provided through such measures as maternity leave with full wages and child benefits.

Fig. 3 summarizes the integrated services delivery package for maternal and newborn care.

**TREATMENT**

From the point of view of treatment, LBW babies can be divided into two groups: (a) those under 2 kg and (b) those between 2-2.5 kg. The first group requires first class modern neonatal care (which is hardly available globally) in an intensive care unit until the weight reaches that of the second group. The second group may need an intensive care unit for a day or two.

**KANGAROO MOTHER CARE**

Kangaroo mother care for low birth-weight babies was introduced in Colombia in 1979 by Drs. Hector Martinez and Edzar Rey as a response to, inter alia, high infection and mortality rates due to overcrowding in hospitals. It has since been adopted across the developing world and has become essential element in the continuum of neonatal care. The four components of kangaroo mother care are all essential for ensuring the best care option, especially for low birthweight babies. They include skin-to-skin positioning of a baby on the mother’s chest; adequate nutrition through breast-feeding; ambulatory care as a result of earlier discharge from hospital; and support for the mother and her family in caring for the baby (37).

The intensive care comprises of: (a) **Incubatory care**: that is, adjustment of temperature, humidity and oxygen supply. There is increasing evidence that low levels of oxygen in a baby’s blood stream (hypoxia) can produce cerebral palsy. Therefore, continuous monitoring of the level of oxygen in baby’s blood stream is now carried out in the best incubatory care units. If the oxygen is excessive, it may lead to retrolental fibroplasia; (b) **Feeding**: Breast-feeding is rarely possible – the baby cannot suck. However, breast milk
should be used if available. Feeding is often by nasal catheter; and (c) Prevention of infection: Infection presents the greatest hazard. Death may occur within a few hours following respiratory infection. Prevention of infection is therefore, one of the most important functions of an intensive care unit.

The leading causes of death in low birth weight babies are:

a. atelectasis.
b. malformation;
c. pulmonary haemorrhage;
d. intracranial bleeding, secondary to anoxia or birth trauma; and

e. pneumonia and other infections.

Facility-based newborn care services like newborn care corner, newborn stabilization unit and special newborn care unit have improved the management of low birth weight babies. Some of these units are linked to obstetric units capable of monitoring the foetus. The development of perinatal intensive care units has been associated with a decline in neonatal mortality.

**FEEDING OF INFANTS**

A detailed discussion of the feeding of infants is outside the scope of this book. However, a brief mention may be made of some of the important aspects of the problem.

**1) Breast-feeding**

Under any circumstances, breast milk is the ideal food for the infant. No other food is required by the baby until 6 months after birth. Under normal conditions, Indian mothers secrete 450 to 600 ml of milk daily with 1.1 gm protein per 100 ml. The energy value of human milk is 70 kcals per 100 ml.

A child who is breast-fed has greater chances of survival than a child artificially fed. Prolonged breast feeding does protect the infant from early malnutrition and some infections. The data suggests that infant mortality rates in developing countries are 5–10 times higher among children who have not been breast-fed or who have been breast-fed for less than 6 months. Despite the marked advantages of breast-feeding, its popularity has declined significantly in many parts of the world.
Advantages of breast-feeding

Among the advantages of breast milk are the following:
1. It is safe, clean, hygienic, cheap and available to the infant at correct temperature;
2. It fully meets the nutritional requirements of the infant in the first few months of life;
3. It contains antimicrobial factors such as macrophages, lymphocytes, secretory IgA, anti-streptococcal factor, lysozyme and lactoferrin which provide considerable protection not only against diarrhoeal diseases and necrotizing enterocolitis, but also against respiratory infections in the first months of life;
4. It is easily digested and utilized by both the normal and premature babies;
5. It promotes "bonding" between the mother and infant;
6. Sucking is good for the baby – it helps in the development of jaws and teeth;
7. It helps in the development of jaws and teeth;
8. It prevents malnutrition and reduces infant mortality;
9. It provides several biochemical advantages such as prevention of neonatal hypocalcaemia and hypomagnesemia (38);
10. It helps parents to space their children by prolonging the period of infertility;
11. Special fatty acids in breast milk lead to increased intelligence quotients and better visual acuity. A breast-fed baby is likely to have an IQ of around 8 points higher than a non-breast fed baby (39).

Early initiation of breast-feeding lowers the mother's risk of postpartum haemorrhage and anaemia, boosts mother's immune system, delays next pregnancy and reduces the insulin of diabetic mothers. It protects mothers from ovarion and breast cancers and osteoporosis (39).

It is neither necessary nor desirable to train a baby to "feed by the clock". It should be explained to the mother, however, that intervals between feeds are necessary for herself and for the baby, though they may vary between 1 to 4 hours, according to the baby's needs, size, strength of sucking and the mother's milk supply.

(2) Artificial feeding

The main indications for artificial feeding are failure of breast milk, prolapsed illness or death of the mother. It is crucial for the baby to be fed "breast-milk substitutes" – e.g., dried whole milk powder, fresh milk from a cow or other animal, or commercial formulae.

PRINCIPLES OF ARTIFICIAL FEEDING

In planning an artificial feed, the nutritional needs of infants should be kept in view. These include:
1. Infants require an average of 100 kcal of energy per kg of body weight per day, i.e., about 150 ml of milk per kg of body weight each day;
2. The estimated protein requirement is about 2.0 g/kg of body weight during the first 6 months; it declines to about 1.5 g/kg by the end of one year. This works out to 13–14 g protein daily during the first year of life. In terms of calories, 8 to 10 per cent of calories are given as protein;
3. The carbohydrate requirement is about 10 g/kg of body weight daily;
4. After 4 months of age, undiluted boiled and cooled milk should be given;
5. Infants need feeding at frequent intervals about 6–8 times a day; older babies 5 times a day; and
6. During illness (e.g., fevers) the calorie need is increased, and it should be met.

(a) DRIED MILK: The safest milk is undoubtedly dried whole milk, which is scientifically prepared for infant feeding. It is free from bacteria; there is little danger from flies; it does not become sour and is simple to reconstitute. It is usually fortified with vitamins. But it is expensive and, therefore, beyond the reach of many Indian families.

(b) COW'S MILK: A cheaper alternative which is well within the reach of many Indian families is cow's milk, which in fact is widely used for infant feeding. Most health workers give very conflicting advice on the use of cow's milk for infant feeding. A small minority of over-enthusiastic paediatricians recommend undiluted cow's milk right from the birth, forgetting the fact that human milk is made for the human baby and cow's milk for the calf. Both cannot be equated. Most authorities in India and abroad including the World Health Organization have persistently recommended dilution of cow's milk during the first 2 months in order to reduce the solute load on neonatal kidneys. The Government of India in the Ministry of Health and Family Welfare in the "Manual for Health Worker (Female) Vol. I (1978) have also recommended dilution of cow's milk during the first two months. A suggested schedule for infant feeding with cow's milk is given in Table 5.

Source: (40)

Artificial feeding is a hazardous procedure in poor homes because of the dangers of contamination and over-dilution of the feed.

The composition of cow's milk and human milk is given in Table 6.

Table 6 shows that cow's milk and human milk are dissimilar in many respects. The differences may be seen as great as the difference between "brain" and "brain".

(a) PROTEIN: One of the striking differences is the low protein content of human milk; this is about 3 times less than in cow's milk and lower than in most mammals. The proteins in human breast milk and cow's milk are completely different. Human milk contains more cystine, essential for the premature, and less methionine than cow's milk. It is rich in taurine, indispensable for infants, but which they, unlike adults, are unable to synthesize. Breast milk is almost completely digested and utilized for growth, whereas much of cow's milk protein is excreted by the infant undigested producing whitish curdy stool. Breast milk contains other proteins whose functions are not nutritive, but anti-infective, e.g., IgG, lysosyme, living cells, etc. Human milk is virtually a "living" fluid.

(b) FATS: Mother's milk is especially rich in fats, which represents between 35–50 per cent of total energy value. There are two main ways in which the fats of human milk differ from those of other milks – first, levels of essential polyunsaturated fatty acids, especially linoleic acid and alpha-linolenic acid are higher in human milk than in cow's milk; secondly, the fats of human milk are easier for the baby...
to digest and absorb than are those of cow's milk. With cow's milk, unabsorbed fatty acids tend to bind with calcium and prevent it from being absorbed. Although there is less calcium in human milk than in cow's milk, it is much better absorbed.

(c) CARBOHYDRATES: Human milk contains more lactose than most other milks. It may be specially useful for the growing brain. In the intestine, lactose helps the "right" kind of bacteria (i.e., *Lactobacillus bifidus*) to grow. Lactobacillus and lactose help to keep the intestinal contents acidic, which inhibits the growth of harmful bacteria. Lactose plays an important role in maintaining low electrolyte concentration.

(d) VITAMINS AND MINERALS: If the mother takes adequate amount of vitamins, there is no reason why the child should have a vitamin supplement. The earlier teaching that human milk was deficient in vitamin D is no longer accepted. Vitamin D is present in human milk in water-soluble form. Human milk contains more vitamin A and vitamin C than cow's milk. Another factor which was supposed to be deficient in human milk was iron, but again recent work has shown that iron contained in human milk has a high level of bioavailability, thanks to complex phenomena (the action of lactoferrin, acidity of the digestive track, presence of appropriate proportions of zinc and copper). The coefficient of uptake of the iron in breast milk may be as high as 70 per cent, whereas it is only 30 per cent for cow's milk and infant formulas (41), and no iron supplement is necessary for the baby reared on human milk. Human milk is richer in copper, selenium and cobalt than cow's milk. It contains less sodium than cow's milk and does not put any unnecessary strain on the infant's kidneys. The calcium/phosphorus ratio is high, so that the uptake of calcium is better than cow's milk. The high phosphorus content of cow's milk causes this mineral to be assimilated to the detriment of calcium. It has the added disadvantage of combining with certain fatty acids to form non-soluble calcium soaps.

WEANING: Weaning is not sudden withdrawal of child from the breast. It is a gradual process starting around the age of 6 months, because the mother's milk alone is not sufficient to sustain growth beyond 6 months. It should be supplemented by suitable foods rich in protein and other nutrients. These are called "supplementary foods". These are usually cow's milk, fruit juice, soft cooked rice, suji, dhal and vegetables. The weaning period is the most crucial period in child development, for during the weaning process children are particularly exposed to the deleterious synergistic interaction of malnutrition and infection. Weaning, if not done properly, is often followed by diarrhea and months of growth failure leading to kwashiorkor, marasmus and immunodeficiency marked by recurrent and persistent infections which may be fatal. A knowledge of weaning foods and practices is an important aspect of preventive and social paediatrics. At the age of one year, the child should receive solid foods consisting of cereals, pulses, vegetables and fruits. There is now enough evidence to show that children can be properly weaned by local foods of a kind usually consumed by the older children and adults in their families. Efforts should therefore be made to design and promote the use of adequate home-made weaning foods.

### Baby friendly hospitals initiatives (2018)

Since 1993 WHO's efforts to improve infant and young child nutrition have focused on promoting breast feeding. It has been calculated that breast feeding could prevent deaths of at least one million children a year. A "baby-friendly hospital initiative" (BFHI), created and promoted by WHO and UNICEF, has proved highly successful in encouraging proper infant feeding practices, starting at birth (42). BFHI is supported by the major professional medical and nursing bodies in India. The implementation guidelines have been revised recently in the year 2018. The ten steps summarize a package of policies and procedures that facilities providing maternity and newborn services should implement to support breastfeeding. The steps are: (1a) Comply fully with the international code of marketing of breast-milk substitutes and relevant World Health Assembly resolutions; (1b) Have a written infant feeding policy that is routinely communicated to staff and parents; (1c) Establish ongoing monitoring and data-management system; (2) Ensure that staff have sufficient knowledge, competence and skills to support breastfeeding; (3) Discuss the importance and management of breastfeeding with pregnant women and their families; (4) Facilitate immediate and uninterrupted skin to skin contact and support mothers to initiate breastfeeding as soon as possible after birth; (5) Support mothers to initiate and maintain breastfeeding and manage common difficulties; (6) Do not provide breastfed newborns any food or fluids other than breast milk, unless medically indicated; (7) Enable mothers and their infants to remain together and to practice rooming-in 24 hours a day; (8) Support mothers to recognize and respond to their infant's cues for feeding; (9) Counsell mothers on the use and risk of feeding bottles, teats and pacifiers; and (10) Coordinate discharge so that parents and their infants have timely access to ongoing support and care (42A). The "Baby friendly" hospitals in India are also expected to adopt and practice guidelines on other interventions critical for child survival including antenatal care, clean delivery practices, essential newborn care, immunization and ORT (43).

PREVENTIVE MEDICINE IN OBSTETRICS, PAEDIATRICS AND GERIATRICS
National guidelines on infant and young child feeding

In view of the vulnerability of young infant to the risk of breast milk substitutes, the Government of India enacted the Infant Milk Substitutes, Feeding Bottles and Infant Food (Regulation of Production, Supply and Distribution) Act 1992. It came into force on 1st Aug. 1993. It prohibits the promotion of infant food, infant milk substitutes and feeding bottles as Government of India is committed to promote breast-feeding.

The new norms of infant and young child feeding i.e., exclusive breast-feeding for the first 6 months (replacing the 4–6 months age range of earlier guidelines), introduction of complementary foods at 6 months while continuing breast-feeding up to the age of 2 years or beyond; replaces the previous policy. The infant milk substitutes, feeding bottles and infant foods (Regulation of Production, Supply and Distribution) Amendment Act 2003, was passed and came into action since 1st January 2004 (39). Goals set to be achieved by year 2007 were:

1. Intensify nutrition and health education to improve infant and child feeding and caring practices so as to (a) bring down the prevalence of under-weight children under three years from the current level of 47 per cent to 40 per cent; (b) reduce prevalence of severe undernutrition in children in the 0–6 years age group by 50 per cent;
2. Enhance early institution of breast feeding (colostrum feeding) from the current level of 15.6 per cent to 50 per cent;
3. Enhance the exclusive breast-feeding rate for the first six months from the current rate of 55.2 per cent to 80 per cent; and
4. Enhance the complementary feeding rate at six months from the current level of 33.5 per cent to 75 per cent.

GROWTH AND DEVELOPMENT

1. Definition

A phenomenon peculiar to the paediatric age group is growth and development. The term growth refers to increase in the physical size of the body, and development to increase in skills and functions. Growth and development are considered together because the child grows and develops as a whole. Growth and development include not only physical aspect, but also intellectual, emotional and social aspects. Normal growth and development take place only if there is optimal nutrition, if there is freedom from recurrent episodes of infections, and if there is freedom from adverse genetic and environmental influences. MCH care is concerned with the process of growth and development, which is the foundation of human life. It is the nature of this process of physical and psychological growth and development of the child which is crucial for health or ill-health, for life or death.

Determinants of growth and development

It is beyond the scope of this book to delve into the subject of growth and development which indeed is a vast one, except to make a passing reference to some of the more important factors influencing it. Briefly these are:

(1) GENETIC INHERITANCE: Genetic factors influence growth and development, especially height and weight, mental and social development and personality.
(2) NUTRITION: Nutrition influences growth and development before as well as after birth. In fact, retardation of growth rate is an indication of malnutrition. When the diet is improved the child begins to grow in height and weight.
(3) AGE: Growth rate is maximum during foetal life, during the first year of life and then again at puberty. At other periods, growth is slower.
(4) SEX: At about the age of 10 to 11 years, female children show a sudden increase in height and weight. This growth spurt corresponds to puberty. In male children, the growth spurt occurs a little later, i.e., between 12 and 13 years.
(5) PHYSICAL SURROUNDINGS: Sunshine, good housing, lighting and ventilation have their effects on growth and development.
(6) PSYCHOLOGICAL FACTORS: Love, tender care and proper child–parent relationship do affect the social, emotional and intellectual development of children.
(7) INFECTIONS AND PARASITOSIS: Certain infections of the mother during pregnancy (e.g., rubella, syphilis) affect the intrauterine growth of the foetus. Infections after birth (e.g., diarrhoea, measles) slow down growth and development, especially in the malnourished child. The intestinal parasites (e.g., roundworms) by consuming considerable quantities of nutrients hamper growth and development.
(8) ECONOMIC FACTORS: The standard of living of the family is an important factor. Children from well-to-do families have better height and weight. The economic factor is connected with the nutrition and living of the people.
(9) OTHER FACTORS: These comprise the birth order of the child, birth spacing, birth weight in single and multiple pregnancies, education of the parents, etc. In short, a normal childhood implies proper physical, mental and emotional development, and is a prerequisite for a full adult life. The study of normal development and its determinants is the basis for paediatric education.

The process of growth from birth to age 20 may be represented diagrammatically in 3 curves (Fig. 4) which shows the level accomplished (as a percentage of development between birth and maturity). These curves are so drawn that height at age 20 corresponds to 100 on the vertical scale. It will be seen from Fig. 4 that the growth of the brain is spectacular during the pre-school age.

2. Normal growth

CONCEPT OF NORMALITY

When speaking of human growth and development, mention must be made of the difficulty of defining normality. A normal child may be defined as one whose characteristics fall within the range of measurements accepted as normal for the majority of children in the same (or reference) age group. Conventionally, these limits — the limits of normal variation — are assumed to include two standard deviations above and below the mean (i.e., between the 3rd and the 97th centiles). This presupposes the availability of accurate measurement techniques of growth, and a satisfactory set of reference values or standards for comparison.

As far as physical development is concerned, we have measurement techniques. For example, we measure growth in terms of kilograms and centimetres. But very great difficulties are encountered in connection with psychomotor, emotional and social development; most measurement techniques are based on observations such as "milestones of development."

Methods of assessment (44, 45)

In children, the parameters of growth generally used are:

- weight, height (or length in infants), and head and chest circumferences. These characteristics are measured and compared with the reference standards. Three methods are generally used for making comparisons:
  1. The first method
is based on mean (or median) values. The median, rather than mean is used where possible because of the skewed distribution of most anthropometric measurements. A variation of 2 standard deviations from either side of the mean (or median) is considered as within normal limits; (ii) The second method is by means of percentile or (centiles). Percentiles are easier to understand than standard deviations. Percentiles refer to the percentage of individuals falling below a particular level. By definition 3 per cent of children are below the 3rd percentile, and a further 3 per cent are above the 97th percentile. The remaining 94 per cent of individuals who fall between these two lines (i.e. between 3rd and 97th percentiles) should therefore be regarded as being within the range of “normal.” However, the 6 per cent of the children outside this range may not necessarily be “abnormal”, particularly if their growth is parallel with their centile lines. A measurement outside 3 standard deviation (above 99th and below 1st centile) is more likely to indicate a significant degree of abnormality; and (iii) Thirdly, it is also possible to assess the growth of a child by such indices as weight for length, and weight for height. These are age-independent indices.

The assessment of growth may be longitudinal or cross-sectional. Longitudinal assessment of growth entails measuring the same child at regular intervals. This provides valuable data about a child’s progress. Cross-sectional studies are also essential to compare a child’s growth with that of his peers. Cross-sectional comparisons involve large number of children of the same age. These children are measured and the range of their measurements (e.g., weight, height) is plotted, usually on percentile charts.

Reference values

For national and international comparisons and for monitoring, reference or “standard” values of growth are essential. The well known reference standards are

- (i) Harvard (or Boston) standards (46) : These are based on observations made on children in Boston from 1930 to 1956. They have been carefully compiled longitudinally on a large series of children, mostly from North European origin. They became widely used throughout the world; (ii) WHO reference values (47, 48) : The Harvard values were replaced by WHO reference values for weight and height. These values were based on extensive cross-sectional data assembled by the United States National Centre for Health Statistics (NCHS) which were considered the best available for international use. The WHO reference values are used for children up to 5 years of age since the influence of ethnic or genetic factors on young children at this age period is considered insignificant, given the similar socio-economic environment; and (iii) Indian standards (49) : The Indian Council of Medical Research (ICMR) undertook a nationwide cross-sectional study during the year 1956 and 1965 to establish the much needed reference standards of growth and development of Indian children, for the country as a whole, as well as for each of the states in the country. As the Indian data are based on measurements of children belonging to the lower socio-economic groups which form the majority of Indian communities, the values cannot be considered as representing standard values (50).

Reference versus standard values

A distinction must be made between reference values and standard values. If the values are derived from a population
racially different from the population under study, such values should be considered as reference values only and not as standard values (52). That is, reference values cannot be used as standard values applicable to a population racially different. For example, it would be absurd to apply the Harvard standards of growth to Pigmies and Eskimos who are racially different (51).

**Surveillance of growth and development**

Surveillance of growth and development is a specific function of the mother and child health services. It is an important component of the routine anticipatory care of children. The main purpose of growth surveillance is to identify those children who are not growing normally. Surveillance also reflects the effectiveness of other components of child care such as nutrition, sanitation and control of infection. Surveillance of growth and development covers the following aspects:

**PHYSICAL GROWTH**

**1. Weight-for-age**

Measurement of weight and rate of gain in weight are the best single parameters for assessing physical growth. A single weight record only indicates the child's size at the moment; it does not give any information about whether a child's weight is increasing, stationary or declining. This is because normal variation in weight at a given age is wide. What is important is careful repeated measurement at intervals ideally monthly, from birth to 1 year, every two months during the second year and every 3 months thereafter up to 5 years of age, since this age group is at greatest risk from growth faltering. By comparing the measurements with reference standards of weight of children of the same age (Table 7), the trend of growth becomes obvious. This is best done on growth chart. Serial weighing is also useful to interpret the progress of growth when the age of the child is not known. Thus, without the aid of a growth chart, it is virtually impossible to detect changes in the rate of growth, such as sudden loss of weight or halt in gain. Each baby should have its own growth chart.

A baby should gain at least 500 gram wt. per month in the first three months of life. That is the minimum. The children who gain less weight are malnourished. It is usual for babies to gain about 1 kg a month, especially in the first 3 months. Healthy babies, on an average double their birth weight by 5 months, and treble it by the end of first year and quadruple by the age of two. During the first year, weight increases by about 7 kg. After that the increase in weight is not so fast — only about 2.5 kg during the second year and from then until puberty by about 2 kg per year. The weight and height gain patterns in India are as shown in Table 8.

In different parts of India, the average birth weight is between 2.7 and 2.9 kg (54). The Indian infant manages to grow well up to the age of 3-4 months, even at the expense of its malnourished mother. Thereafter, the growth falters due to lack of supplementary feeding (55). However, Indian children from well-to-do families display growth patterns as good as their counterparts in the Western world (49).

Source: (53)
Weight-for-age is often used to classify malnutrition and determine its prevalence. Jelliffe suggested that 80 per cent of the median weight-for-age of the reference be the cut-off point below which children could be considered malnourished.

2. Height (length)-for-age

Height should be taken in a standing position without foot wear. If the height machine is not available, the measuring scale fixed to the wall can be employed. This arrangement is suitable for children 2 years and above. The measuring scale should be capable of measuring to an accuracy of 0.1 cm. A very great effort should be made to measure children accurately. Errors in the measurement of a young child may lead to significant errors in the classification of the nutritional status. The WHO standards (2006) for height-for-age are as shown in Table 9.

The length of a baby at birth is about 50 cm. It increases by about 25 cm during first year, and by another 12 cm during the second year. During growth spurt, boys add something like 20 cm in their height, and girls gain about 16 cm. The spurt is followed by a rapid slowing of growth. Indian girls reach 98 per cent of their final height on an average by the age of 16.5 years, and boys reach the same stage by the age of 17.75 years. With the exception of a few ethnic groups, there is evidence showing that all children have a similar growth potential.

Height is a stable measurement of growth as opposed to body weight. Whereas weight reflects only the present health status of the child, height indicates the events in the past also. The use of growth (height) centile chart is particularly valuable in studying the trend of height curve.

Low height for age: This is also known as nutritional stunting or dwarfing. It reflects past or chronic malnutrition. The cut-off point commonly taken for the diagnosis of stunting is 90 per cent of the United States NCHS height-for-age values. Waterlow recorded the use of 2SD below the median reference as the cut-off point.

Weight records

Weight records are generally kept by all infant clinics; the aim is the prevention of underfeeding, and in the developing world, the weight chart is an important tool in the prevention of malnutrition.

4. Head and chest circumference

At birth the head circumference is about 34 cm. It is about 2 cm more than the chest circumference. By 6 to 9 months, the two measurements become equal, after which the chest circumference overtakes the head circumference. In severely malnourished children, this overtaking may be delayed by 3 to 4 years due to poor development of the thoracic cage. In ICMR study, the crossing over of chest and head circumference did not take place until the age of two years and six months. This has been attributed to growth retardation in poor Indian children.

Besides increase in height and weight, the term "growth" also includes various physiological events which occur at predictable periods such as, dentition, ossification of bones and secondary sexual characteristics.

BEHAVIOURAL DEVELOPMENT

A closely related development is behavioural development. It is assessed in four fields.
can be expected to attain certain skills or points in
devolution. Since the milestone are averages, each child is
bound to differ from the other. For instance, some children
sit up and speak earlier than others. Table 10 shows some of
the normal developmental milestones and ages at which
these are reached in the Indian context. When a child takes
longer time to cross these milestones, the possibility of his
behaving mentally handicapped should not be overlooked.

The behavioural development of the child is a complex
affair. The work of ethologists and sociologists show how
quickly the child's behaviour conform to the models adult
society offers them. For proper behaviour development, the
child must be ensured emotional and moral stability, that is,
a home where he will find bonds of affection, regular
discipline and parents who accept him and provide him with
models of balanced conduct. Many children will not
find themselves in ideal conditions. They consequently
have trouble with behaviour, speech, sleep and appetite
and these problems will have to be anticipated, diagnosed
and treated.

THE GROWTH CHART

The growth or “road-to-health” chart (first designed by
David Morley and later modified by WHO) is a visible display
of the child’s physical growth and development. It is designed
primarily for the longitudinal follow-up (growth monitoring)
of a child, so that changes over time can be interpreted.

It is important to note that in the weight-for-age chart, the
height of the child is not taken into consideration. This is
because weight is the most sensitive measure of growth, and
any deviation from “normal” can be detected easily by
comparison with reference curves. A child can lose
weight, but not height. In short, the growth chart offers a
simple and inexpensive way of monitoring weight gain, and
in fact child health over time.

1. WHO child growth standards, 2006 (53)

In 1993 the WHO undertook a comprehensive review of
the uses and interpretation of anthropometric references.
The review concluded that the NCHS growth references,
which had been recommended for international use since
the late 1970s, did not adequately represent early childhood
growth and that new growth curves were necessary. A
Multicentre Growth Reference Study (MGSR) was
undertaken between 1997 and 2003 in Brazil, Ghana, India,
Norway, Oman and USA and primary growth data and
related information were gathered from 9,440 healthy
breast-fed infants and young children (0 to 60 months boys
and girls) from widely diverse ethnic background and
cultural settings. In addition their mothers followed health
practices such as breast feeding their children, and not
smoking during and after pregnancy.

The new standards were generated for boys and girls
aged 0–60 months – percentile and Z-score curves for
length/height-for-age, weight-for-age, weight-for-length,
weight-for-height and BMI-for-age. The last standard is an
addition of the set of indicators previously available as part
of the NCHS WHO reference.

As expected, there are notable differences with the
NCHS/WHO reference that vary by age, sex, anthropometric measure and specific percentile or Z-score curve. Differences are particularly important in infancy. Stunting will be greater throughout childhood when assessed using the new WHO standards compared to the NCHS/WHO reference. The growth pattern of breast-fed infant will result in a substantial increase in rates of underweight during the first half of infancy and a decrease thereafter. For wasting, the main difference is during infancy when wasting rate will be substantially higher using the new WHO standards. With respect to overweight, use of the new standards will result in a greater prevalence that will vary by age, sex and nutritional status of the index population.

The new WHO standards depict normal early childhood
growth under optimal environmental conditions and can be
used to assess children everywhere, regardless of ethnicity,
socio-economic status and type of feeding.

Fig. 5 and 6 show the comparison of WHO with NCHS
weight-for-age reference curve from birth to 5 years of age
for boys and girls respectively (53).

2. Growth chart used in India

India has adopted the new WHO Child Growth Standards (2006) in February 2009, for monitoring the young child growth and development within the National Rural Health Mission and the ICDS. The same standards will be used for research too in future.

These standards are available for both boys and girls below 5 years of age. With these new standards the child care workers will know when the nutrition and care needs of the child is being compromised and it will enable them to take timely corrective action at different levels.

A joint “Mother and Child Protection Card” has been developed, as shown in Fig. 7 and 8, which provides space for recording the family identification and registration, birth record, pregnancy record, institutional identification, care during pregnancy, preparation for delivery, registration under Janani Suraksha Yojana, details about immunization procedures, breast-feeding and introduction of supplementary food, milestones of the baby, birth spacing and reasons for special care. The chart is easily understood by the health workers and the mother, with a visual record of the health and nutritional status of the child. It is kept by the mother and brought to the health centre at each visit.

The growth chart shows normal zone of weight for age, undernutrition (below – 2 SD) and severely underweight zone (below – 3 SD). In some states like Maharashtra, the growth chart contains normal weight for age zone and undernutrition zone of grade one, second, third and fourth. It is the direction of growth that is more important than the position of dots on the line. The importance of the direction of growth is illustrated at the left hand, upper corner of the chart. Flattening or falling of the child’s weight curve signals growth failure, which is the earliest sign of the protein-energy malnutrition and may precede clinical signs by weeks and months. Such a child needs special care. The objective in child care is to keep the child in normal zone.

Have your child weighed at the AWC every month

**FIG. 7**

ICDS growth chart for boys
**Uses of growth chart**

A growth chart has many potential uses:

1. for **growth monitoring** which is of great value in child health care;
2. **diagnostic tool**: for identifying "high-risk" children. For example, malnutrition can be detected long before signs and symptoms of it become apparent.
3. **planning and policy making**: by grading malnutrition, it provides an objective basis for planning and policy making in relation to child health care at the local and central levels;
4. **educational tool**: because of its visual character, the mother can be educated in the care of her own child and encourage her to participate more actively in growth monitoring;
5. **tool for action**: it helps the health worker on the type of intervention that is needed; it will help to make referrals easier;
6. **evaluation**: it provides a good method to evaluate the effectiveness of corrective measures and the impact of a programme or special interventions for improving child growth and development; and
7. **tool for teaching**: it can also be used for teaching, for example, the importance of adequate feeding; the deleterious effects of diarrhoea.

The growth chart has been described as a passport to child health care (57). It has won international recognition and is now a standard method of monitoring children's health and nutritional status.

**Alternative methods of growth monitoring**

Growth charting is only one method of growth monitoring. There are other indicators such as height-for-
Birth and death rates

The birth and death rates are important components of population growth. The birth and death rates in India are shown in Table 18. A look at Table 18 shows that whereas the death rate has considerably declined from 27.4 in 1951 to an estimated 6.4 per thousand population in 2016, the birth rate has declined niggardly from 39.9 in 1951 to an estimated 20.4 per thousand in 2016.

The Fifth Five Year (1974-79) Plan's objective was to reduce the birth rate from 35 per thousand at the beginning of the Plan to 30 per thousand by 1978-79. During 1979-84, the birth rate was stagnating around 33 per thousand with no obvious decline. During 1990, however, the birth rate showed a slight decline, to an estimated 30.2, further declining to 26.4 by the year 1998. The current picture indicates that birth and death rates are both declining in India.

Source: (8)

HIGH BIRTH RATE: India like other developing countries is faced with the dilemma of a high birth rate and a declining death rate. This is a vicious circle, not easy to break. The causes of high birth rate are:

1. **Universalism of marriage**: Marriages are universal and sacramental. Everyone, sooner or later (usually sooner) gets married and participates in reproduction. The individual's economic security or emotional maturity are seldom a pre-requisite to marriage.

2. **Early marriage**: Marriages are performed early. Data indicate that about 60 per cent of the girls aged 15-19 years are already married.

3. **Early puberty**: Indian girls attain puberty early, between 12 and 14 years.

4. **Low standard of living**: Where standards of living are low, birth rates are high.

5. **Low level of literacy**: The 2011 census showed that only 74.04 per cent of the population was literate. The female literacy is still lower, especially in the rural areas.

6. **Traditional customs and habits**: Customs dictate that every woman must marry and every man must have a son. Children are considered a gift of God and their birth should not be obstructed.

7. **Absence of family planning habit**: Family planning is of recent origin. It has not yet become a part of the marital mores of the people.

DECLINING DEATH RATE: The declining death rate has been attributed to:

1. Absence of natural checks, e.g., famines and large scale epidemics.
2. Mass control of...
demands, e.g., smallpox, plague, cholera, malaria etc., (3) advances in medical science, e.g., extensive use of chemotherapeutics, antibiotics, and insecticides, (4) better health facilities, e.g., establishment of primary health centres and more treatment centres, (5) impact of national health programmes, (6) improvements in food supply, (7) international aid in several directions, and (8) development of social consciousness among the masses.

Demographers opine that further rapid decline in India's death rate may not continue in future. The reason is that most of the "easy" conquest of mortality has been accomplished through the widespread use of vaccines, antibiotics, insecticides, and other life-saving measures. The tasks that remain now are the most difficult ones such as improvements in environmental sanitation and nutrition; and control of non-communicable and genetic diseases.

**Growth rate**

The population growth rates in India are presented in Table 6. Prior to 1921, the population of India grew at a slow rate. This was due to the operation of natural checks (e.g., famines and epidemics) which took a heavy toll of human life. After 1921, the "great divide", the occurrence of famines and epidemics was effectively controlled through better nutrition and improved health care services, with the result that the death rate declined more steeply than the birth rate. Consequently, there was a net gain in births over deaths, leading to rapid growth in population, which rose from 1.25 per cent in 1951 to 1.95 in 1961, 2.20 in 1971, 2.22 in 1981, 2.14 in 1991, 1.93 in 2001 and 1.64 in 2011 (Table 6).

India is now the second most populous country in the world, adding 17.5 million every year to her 1.210 million at the time of 2011 census. However, the most recent data indicates a decline in India's population growth rate. The estimates for the year 2017 is 1.2.

**FAMILY PLANNING**

**Definition**

There are several definitions of family planning. An Expert Committee (1971) of the WHO defined family planning as "a way of thinking and living that is adopted voluntarily, upon the basis of knowledge, attitudes and responsible decisions by individuals and couples, in order to promote the health and welfare of the family group and thus contribute effectively to the social development of a country" (24).

Another Expert Committee (25) defined and described family planning as follows: "Family planning refers to practices that help individuals or couples to attain certain objectives:

(a) to avoid unwanted births;
(b) to bring about wanted births;
(c) to regulate the intervals between pregnancies;
(d) to control the time at which births occur in relation to the ages of the parent; and
(e) to determine the number of children in the family.

**Basic human rights**

The United Nations Conference on Human Rights at Teheran in 1968 recognized family planning as a basic human right. The Bucharest Conference (26) on the World Population held in August 1974 endorsed the same view and stated in its 'Plan of Action' that "all couples and individuals have the basic human right to decide freely and responsibly the number and spacing of their children and to have the information, education, and means to do so". The World Conference of the International Women's Year in 1975 also declared "the right of women to decide freely and responsibly on the number and spacing of their children and to have access to the information and means to enable them to exercise that right" (27). Thus during the past few decades, family planning has emerged from whispers in private quarters to the focus of international concern as a basic human right, and a component of family health and social welfare.

**Scope of family planning services**

Family planning is not synonymous with birth control; it is more than mere birth control. A WHO Expert Committee (1970) has stated that family planning includes in its purview: (1) the proper spacing and limitation of births, (2) advice on sterility, (3) education for parenthood, (4) sex education, (5) screening for pathological conditions related to the reproductive system (e.g., cervical cancer), (6) genetic counselling, (7) premarital consultation and examination, (8) carrying out pregnancy tests, (9) marriage counselling, (10) the preparation of couples for the arrival of their first child, (11) providing services for unmarried mothers, (12) teaching home economics and nutrition, and (13) providing adoption services. These activities vary from country to country according to national objectives and policies with regard to family planning. This is the modern concept of family planning.

**Health aspects of family planning**

Family planning and health have a two-way relationship. The principal health outcomes of family planning were listed and discussed by a WHO Scientific Group on the Health Aspects of Family Planning (28). These can be summarized under the following headings.

**Women's health**

maternal mortality, morbidity of women of child-bearing age, nutritional status (weight changes, haemoglobin level, etc.) preventable complications of pregnancy and abortion.

**Foetal health**

foetal mortality (early and late foetal death); abnormal development.

**Infant and child health**

neonatal, infant and pre-school mortality, health of the infant at birth (birth weight), vulnerability to diseases.

(a) **WOMEN'S HEALTH** : Pregnancy can mean serious problems for many women. It may damage the mother's health or even endanger her life. In developing countries, the risk of dying as a result of pregnancy is much greater than in developed countries. The risk increases as the mother grows older and after she has had 3 or 4 children. Family planning by intervening in the reproductive cycle of women, helps them to control the number, interval and timing of pregnancies and births, and thereby reduces maternal mortality and morbidity and improves health. The health impact of family planning occurs primarily through:

(i) the avoidance of unwanted pregnancies; (ii) limiting the number of births and proper spacing, and (iii) timing the births, particularly the first and last, in relation to the age of
by 25 per cent, and child mortality by 20 per cent (10).

(i) Unwanted pregnancies: The essential aim of family planning is to prevent the unwanted pregnancies. An unwanted pregnancy may lead to an induced abortion. From the point of view of health, abortion outside the medical setting (criminal abortion) is one of the most dangerous consequences of unwanted pregnancy. Particular mention must be made of the unmarried mother who faces significantly higher health risks. There is also evidence of higher incidence of mental disturbances among mothers who have had unwanted pregnancies.

(ii) Limiting the number of births and proper spacing: Repeated pregnancies increase the risk of maternal mortality and morbidity. These risks rise with each pregnancy beyond the third, and increase significantly with each pregnancy beyond the fifth. The incidence of rupture of the uterus and uterine atony increases with parity as does the incidence of toxemia, eclampsia and placenta previa. Anaemia is a common problem in mothers with many children and the rate of stillbirths tends to increase significantly with high parity. The somatic consequences of repeated pregnancies may also be exemplified in the clear association between the incidence of cancer of the cervix and high parity. Family planning is the only way to limit the size and control the interval between births with a view to improving the health of the mother.

(iii) Timing of births: Generally mothers face greater risk of dying below the age of 20 and above the age of 30–35. In many countries, complications of pregnancy and delivery show the same pattern of risk, with the highest rate below 20 and over 35 years of age.

(b) Foetal health: A number of congenital anomalies (e.g., Down’s syndrome) are associated with advancing maternal age. Such congenital anomalies can be avoided by timing the births in relation to the mother’s age. Further, the “quality” of population can be improved only by avoiding completely unwanted births. In the present state of our knowledge, it is very difficult to weigh the overall genetic effects of family planning.

(c) Child health: Issues relating to family planning are highly relevant to pediatrics. It would seem that family size and birth spacing, if practised by all, will yield substantial child health benefits. These are: (a) Child mortality: It is well known that child mortality increases when pregnancies occur in rapid succession. A birth interval of 2 to 3 years is considered desirable to reduce child mortality. Family planning, therefore, an important means of ensuring the survival of all children in a family. (b) Child growth, development and nutrition: Birth spacing and family size are important factors in child growth and development. The child is likely to receive his full share of love and care, including nutrition he needs, when the family size is small and births are properly spaced. Family planning, in other words, is effective prevention against malnutrition. (c) Infectious diseases: Children living in large-sized families have an increase in infection, especially Infectious gastroenteritis, respiratory and skin infections.

The welfare concept

Family planning is associated with numerous misconceptions – one of them is its strong association in the minds of people with sterilization. Others equate it with birth control. The recognition of its welfare concept came only a decade and half after its inception, when it was named Family Welfare Programme.

The concept of welfare is very comprehensive and is basically related to quality of life. The Family Welfare Programme aims at achieving a higher end – that is, to improve the quality of life of the people.

Small-family norm

Small differences in the family size will make big differences in the birth rate. The difference of only one child per family over a decade will have a tremendous impact on the population growth.

The objective of the Family Welfare Programme in India is that people should adopt the “small family norm” to stabilize the country’s population at the level of some 1,533 million by the year 2050 AD. Symbolized by the inverted red triangle, the programme initially adopted the model of the 3–child family. In the 1970s, the slogan was the famous Do Ya Teen Bas. In view of the seriousness of the situation, the 1980s campaign has advocated the 2–child norm. The current emphasis is on three themes: “Sons or Daughters – two will do”; “Second child after 3 years”, and “Universal Immunization”.

A significant achievement of the Family Welfare Programme in India has been the decline in the fertility rate from 6.4 in the 1950s to 2.3 in 2016. The national target was to achieve a Net Reproduction Rate of ‘1’ by the year 2006, which is equivalent to attaining approximately the 2–child norm. All efforts are being made through mass communication that the concept of small family norm is accepted, adopted and woven into lifestyle of the people.

Eligible couples

An “eligible couple” refers to a currently married couple wherein the wife is in the reproductive age, which is generally assumed to lie between the ages of 15 and 45. There will be at least 150 to 180 such couples per 1000 population in India. These couples are in need of family planning services. About 20 per cent of eligible couples are found in the age group 15–24 years (31). On an average 2.5 million couples are joining the reproductive group every year. The “Eligible Couple Register” is a basic document for organizing family planning work. It is regularly updated by each functionary of the family planning programme for the area falling within his jurisdiction.

The scenario in India as on March, 2011 is as shown in Fig. 6.

![Fig. 6](image-url)

Estimated eligible couples and target couples in India.
Target couples

In order to pin-point the couples who are a priority group within the broad definition of “eligible couples”, the term “target couple” was coined. Hitherto, the term target couple was applied to couples who have had 2-3 living children, and family planning was largely directed to such couples. The definition of a target couple has been gradually enlarged to include families with one child or even newly married couples (34) with a view to develop acceptance of the idea of family planning from the earliest possible stage. In effect, the term target couple has lost its original meaning. The term eligible couple is now more widely used and has come to stay.

Couple protection rate (CPR)

Couple protection rate (CPR) is an indicator of the prevalence of contraceptive practice in the community. It is defined as the per cent of eligible couples effectively protected against childbirth by one or the other approved methods of family planning viz. sterilization, IUD, condom or oral pills. Sterilization accounts for over 60 per cent of effectively protected couples (31). Demographers are of the view that the demographic goal of NRR = 1 can be achieved only if the CPR exceeds 60 per cent.

Couple protection rate is based on the observation that 50 to 60 per cent of births in a year are of birth order 3 or more. Thus attaining a 60 per cent CPR will be equivalent to cutting off almost all third or higher order births, leaving 2 or less surviving children per couple (33). Therefore, the previous National Population Policy was to attain a CPR of 42 per cent by 1990 (end of Seventh Five Year Plan), and 60 per cent by the year 2000. In short CPR is a dominant factor in the reduction of net reproduction rate.

During 2014–2015, the total number of family planning acceptors by different methods was as follows (34A).

- Sterilization .... 4.03 million
- Vasectomy .... 0.07 million
- Tubectomy .... 3.95 million
- IUD insertion .... 5.28 million
- Condom users .... 13.81 million
- Oral pill users .... 5.6 million

However about 45.28 per cent eligible couples are still unprotected against conception.

During 2015–2016, about 53.5 per cent of eligible couples in the reproductive age group 15–44 years were effectively protected against conception by one or the other family planning method.

A state-wise break-up of the figures reported indicates that while some states notably Punjab, Gujarat, Maharashtra, Karnataka, Haryana and Tamil Nadu etc. are forging ahead to cover more than half of their fertility level population by contraception, the other states like Bihar, Uttar Pradesh, Assam, Rajasthan, West Bengal, Jammu and Kashmir etc. are lagging behind with low contraceptive acceptance levels.

NATIONAL POPULATION POLICY 2000

Population policy in general refers to policies intended to decrease the birth rate or growth rate. Statement of goals, objectives and targets are inherent in the population policy.

In April 1976 India formed its first – "National Population Policy". It called for an increase in the legal minimum age of marriage from 15 to 18 for females, and from 18 to 21 years for males. However, for the most part, the 1976 statement became irrelevant and the policy was modified in 1977. New policy statement reiterated the importance of the small family norm without compulsion and changed the programme title to "family welfare programme". The National Health Policy approved by the parliament in 1983 had set the long-term demographic goals of achieving a Net Reproductive Rate (NRR) of one by the year 2000 (which was not achieved).

“National Population Policy 2000” is the latest in this series. It reaffirms the commitment of the government towards targeted free approach in administering family planning services. It gives informed choice to the people to voluntarily avail the reproductive health care services.

The new NPP 2000 is more than just a matter of fertility and mortality rates. It deals with women education; empowering women for improved health and nutrition; child survival and health; the unmet needs for family welfare services; health care for the under-served population groups like urban slums, tribal community, hill area population and displaced and migrant population; adolescent’s health and education; increased participation of men in planned parenthood; and collaboration with NGOs.

The objective of NPP 2000 is to bring the TFR to replacement level by 2010. The long term objective is to achieve requirements of suitable economic growth, social development and environment protection.

The National Socio-Demographic Goals to be achieved by the year 2010 were as follows (35):

1. Address the unmet needs for basic reproductive and child health services, supplies and infrastructure.
2. Make school education up to the age 14 free and compulsory, and reduce drop-outs at primary and secondary school levels to below 20 per cent for both boys and girls.
3. Reduce infant mortality rate to below 30 per 1000 live births.
4. Reduce maternal mortality ratio to below 100 per 100,000 live births.
5. Achieve universal immunization of children against all vaccine preventable diseases.
6. Promote delayed marriage for girls, not earlier than age 18 and preferably after 20 years of age.
7. Achieve 80 per cent institutional deliveries and 100 per cent deliveries by trained persons.
8. Achieve universal access to information/counselling, and services for fertility regulation and contraception with a wide basket of choices.
9. Achieve 100 per cent registration of births, deaths, marriage and pregnancy.
10. Contain the spread of Acquired Immunodeficiency Syndrome (AIDS), and promote greater integration between the management of reproductive tract infections (RTI) and sexually transmitted infections (STI) and the National AIDS Control Organization.
11. Prevent and control communicable diseases.
12. Integrate Indian Systems of Medicine (ISM) in the provision of reproductive and child health services, and in reaching out to households.
(13) Promote vigorously the small family norm to achieve replacement levels of TFR.

(14) Bring about convergence in implementation of related social sector programmes so that family welfare becomes a people centred programme.

If the NPP 2000 was fully implemented, it was anticipated that in the year 2010 the population may be 1107 million instead of 1162 million projected by the Technical Group of Population Projections. However, the provisional population (1210 million) in 2011 is higher by about 110 million compared to the target set for the year 2010. Efforts at population stabilization will be effective only if an integrated package of essential services is directed at village and household levels. Inadequacies in the existing health infrastructure have led to a unmet need of 28 per cent of contraception services and obvious gap in coverage and outreach. The NPP 2000 is to be largely implemented and managed at panchayat and nagar palika levels in coordination with the concerned state/UT administration.

**CONTRACEPTIVE METHODS**

(Fertility Regulating Methods)

Contraceptive methods are, by definition, preventive methods to help women avoid unwanted pregnancies. They include all temporary and permanent measures to prevent pregnancy resulting from coitus.

The last few years have witnessed a contraceptive revolution, that is, man trying to interfere with the ovulation cycle.

It is now generally recognized that there can never be an ideal contraceptive — that is, contraceptive that is safe, effective, acceptable, inexpensive, reversible, simple to administer, independent of coitus, long-lasting enough to obviate frequent administration and requiring little or no medical supervision. Further, a method which may be quite suitable for one group may be unsuitable for another because of different cultural patterns, religious beliefs and socio-economic milieu. As there is no single method likely to meet the social, cultural, aesthetic and service needs of all individuals and communities, the search for an "ideal contraceptive" has been given up. The present approach in family planning programmes is to provide a "cafeteria choice" that is to offer all methods from which an individual can choose according to his needs and wishes and to promote family planning as a way of life.

The term conventional contraceptives is used to denote those methods that require action at the time of sexual intercourse, e.g., condoms, spermicides, etc. Each contraceptive method has its unique advantages and disadvantages. The success of any contraceptive method depends not only on its effectiveness in preventing pregnancy but on the rate of continuation of its proper use.

The contraceptive methods may be broadly grouped into two classes — spacing methods and terminal methods, as shown below:

### I. Spacing methods

1. Barrier methods
   - a. Physical methods
   - b. Chemical methods
   - c. Combined methods

2. Intra-uterine devices
3. Hormonal methods
4. Post-conceptional methods
5. Miscellaneous.

### II. Terminal methods

1. Male sterilization
2. Female sterilization.

**BARRIER METHODS**

A variety of barrier or "occlusive" methods, suitable for both men and women are available. The aim of these methods is to prevent live sperm from meeting the ovum. Barrier methods have increased in popularity quite recently because of certain contraceptive and non-contraceptive advantages. The main contraceptive advantage is the absence of side-effects associated with the "pill" and IUD. The non-contraceptive advantages include some protection from sexually transmitted diseases, a reduction in the incidence of pelvic inflammatory disease and possibly some protection from the risk of cervical cancer (36). Barrier methods require a high degree of motivation on the part of the user. In general they are less effective than either the pill or the loop. They are only effective if they are used consistently and carefully.

**a. PHYSICAL METHODS**

1. **Condom** (37, 38)

   Condom is the most widely known and used barrier device by the males around the world. In India, it is better known by its trade name NIRODH, a sanskrit word, meaning prevention. Condom is receiving new attention today as an effective, simple "spacing" method of contraception, without side effects. In addition to preventing pregnancy, condom protects both men and women from sexually transmitted diseases.

   The condom is fitted on the erect penis before intercourse. The air must be expelled from the teat end to make room for the ejaculate. The condom must be held carefully when withdrawing it from the vagina to avoid spilling seminal fluid into the vagina after intercourse. A new condom should be used for each sexual act.

   Condom prevents the semen from being deposited in the vagina. The effectiveness of a condom may be increased by using it in conjunction with a spermicidal jelly inserted into the vagina before intercourse. The spermicide serves as an additional protection in the unlikely event that the condom should slip off or tear.

   Condoms can be a highly effective method of contraception, if they are used correctly at every coitus. Failure rates for the condom vary enormously. Surveys have reported pregnancy rates varying from 2–3 per 100 women-years to more than 14 in typical users (39). Most failures are due to incorrect use.

   The ADVANTAGES of condom are: (a) they are easily available (b) safe and inexpensive (c) easy to use; do not require medical supervision (d) no side effects (e) light, compact and disposable, and (f) provides protection not only against pregnancy but also against STD.
DISADVANTAGES are: (a) it may slip off or tear during coitus due to incorrect use, and (b) interferes with sexual sensation locally about which some complain while others get used to it. The main limitation of condoms is that many men do not use them regularly or carefully, even when the risk of unwanted pregnancy or sexually transmitted disease is high.

Condoms are manufactured in India by the Hindusthan Latex in Trivandrum, London Rubber Industries in Chennai and others. Besides commercial outlets, condoms are supplied under social marketing programme.

Female condom

The female condom is a pouched made of polyurethane, which lines the vagina. An internal ring in the close end of the pouch covers the cervix and an external ring remains outside the vagina. It is prelubricated with silicon, and a spermicide need not be used. It is an effective barrier to STD infection. However, high cost and acceptability are major problems. The failure rates during the first year use vary from 5 per 100 women-years pregnancy rate to about 21 in typical users (40).

2. Diaphragm

The diaphragm is a vaginal barrier. It was invented by a German physician in 1882. Also known as “Dutch cap”, the diaphragm is a shallow cup made of synthetic rubber or plastic material. It ranges in diameter from 5–10 cm (2–4 inches). It has a flexible rim made of spring or metal. It is important that a woman be fitted with a diaphragm of the proper size. It is held in position partly by the spring tension and partly by the vaginal muscle tone. This means, for successful use, the vaginal tone must be reasonable. Otherwise, in the case of a severe degree of cystocele, the rim may slip down.

The diaphragm is inserted before sexual intercourse and must remain in place for not less than 6 hours after sexual intercourse. A spermicidal jelly is always used along with the diaphragm. The diaphragm holds the spermicide over the cervix. Side-effects are practically nil. Failure rate for the diaphragm with spermicide vary between 6 to 12 per 100 women-years (39).

ADVANTAGES: The primary advantage of the diaphragm is the almost total absence of risks and medical contraindications. DISADVANTAGES: Initially a physician or other trained person will be needed to demonstrate the technique of inserting the diaphragm into the vagina and to ensure a proper fit. After delivery, it can be used only after involution of the uterus is completed. Practice at insertion, privacy for this to be carried out and facilities for washing and storing the diaphragm precludes its use in most Indian families, particularly in the rural areas. Therefore, the extent of its use has never been great.

If the diaphragm is left in the vagina for an extended period, there is a remote possibility of a toxic shock syndrome, which is a state of peripheral shock requiring resuscitation (41).

Variations of the diaphragm include the cervical cap, vault cap and the vimule cap. These devices are not recommended in the National Family Welfare Programme.

3. Vaginal sponge

Another barrier device employed for hundreds of years is the sponge soaked in vinegar or olive oil, but it is only recently one has been commercially marketed in USA under the trade name TODAY for the sole purpose of preventing conception. It is a small polyurethane foam sponge measuring 5 cm x 2.5 cm, saturated with the spermicide, nonoxynol-9. The sponge is far less effective than the diaphragm, but it is better than nothing (42). The failure rate in parous women is between 20 to 40 per 100 women-years and in nulliparous women about 9 to 20 per 100 women-years (40).

b. CHEMICAL METHODS

In the 1960s, before the advent of IUDs and oral contraceptives, spermicides (vaginal chemical contraceptives) were used widely. They comprise four categories (43):

a. Foams: foam tablets, foam aerosols
b. Creams, jellies and pastes – squeezed from a tube
c. Suppositories – inserted manually, and
d. Soluble films – C-film inserted manually

The spermicides contain a base into which a spermicide is incorporated. The commonly used modern spermicides are “surface-active agents” which attach themselves to spermatozoa and inhibit oxygen uptake and kill sperms (44).

The main drawbacks of spermicides are: (a) they have a high failure rate (b) they must be used almost immediately before intercourse and repeated before each sexual act (c) they must be introduced into those regions of the vagina where sperms are likely to be deposited, and (d) they may cause mild burning or irritation, besides messiness. The spermicide should be free from potential systemic toxicity. It should not have an inflammatory or carcinogenic effect on the vaginal skin or cervix. No spermicide which is safe to use has yet been found to be really effective in preventing pregnancy when used alone (44). Therefore, spermicides are not recommended by professional advisers. They are best used in conjunction with barrier methods. Recently there has been some concern about possible teratogenic effects on foetuses, following their use. However, this risk is yet to be confirmed (41).

INTRA-UTERINE DEVICES

Types of IUD

There are two basic types of IUD: non-medicated and medicated. Both are usually made of polyethylene or other polymers; in addition, the medicated or bioactive IUDs release either metal ions (copper) or hormones (progestogens).

The non-medicated or inert IUDs are often referred to as first generation IUDs. The copper IUDs comprise the second and the hormone—releasing IUDs the third generation IUDs. The medicated IUDs were developed to reduce the incidence of side-effects and to increase the contraceptive effectiveness. However, they are more expensive and must be changed after a certain time to maintain their effectiveness (45). Fig. 7 shows different types of IUDs currently in use. In India, under the National Family Welfare Programme, Cu—T—200 B is being used. From the year 2002, Cu—T—380 A has been introduced in the programme (46).
FIRST GENERATION IUDs

The first generation IUDs comprise the inert or non-medicated devices, usually made of polyethylene, or other polymers. They appeared in different shapes and sizes — loops, spirals, coils, rings, and bows. Of all the models, the Lippes Loop is the best known and commonly used device in the developing countries.

Lippes Loop

Lippes Loop is double-S shaped device made of polyethylene, a plastic material that is non-toxic, non-tissue reactive and extremely durable. It contains a small amount of barium sulphate to allow X-ray observation. The Loop has attached threads or “tail” made of fine nylon, which project into the vagina after insertion. The tail can be easily felt and is a reassurance to the user that the Loop is in its place. The tail also makes it easy to remove the Loop when desired.

The Lippes Loop exists in four sizes A, B, C, and D, the latter being the largest. A larger sized device usually has a greater anti-fertility effect and a lower expulsion rate but a higher removal rate because of side-effects such as pain and bleeding. The larger Loops (C and D) are more suitable for multiparous women.

SECOND GENERATION IUDs

It occurred to a number of research workers that the ideal IUD can never be developed simply as a result of obtaining changes in the usual shape or size (42). A new approach was tried in the 1970s by adding copper to the IUD. It was found that metallic copper had a strong anti-fertility effect (47). The addition of copper has made it possible to develop smaller devices which are easier to fit, even in nulliparous women. A number of copper bearing devices are now commercially available:

Earlier devices:
- Copper-7
- Copper T-200

Newer devices:
- Variants of the T device
  - Cu-T-220 C
  - Cu-T-380 A or Ag
- Nova T
- Multiload devices
  - ML-Cu-250
  - ML-Cu-375

The numbers included in the names of the devices refer to the surface area (in sq. mm) of the copper on the device. Nova T and Cu-T-380 Ag are distinguished by a silver core over which the copper wire is wrapped.

The newer copper devices are significantly more effective in preventing pregnancy than the earlier copper ones or the inert IUDs. The newer copper IUDs — Multiload devices and variants of the T device — offer the further advantage of having an effective life of at least 5 years. They can be left in place safely for the time, unless specific medical or personal reasons call for earlier removal.

Advantages of copper devices
- Low expulsion rate
- Lower incidence of side-effects, e.g., pain and bleeding
- Easier to fit even in nulliparous women
- Better tolerated by nullipara
- Increased contraceptive effectiveness
- Effective as post-coital contraceptives, if inserted within 3-5 days of unprotected intercourse

THIRD GENERATION IUDs

A third generation of IUDs — based on still another principle, i.e., release of a hormone — have become available on a limited scale. The most widely used hormonal device is progestasert, which is a T-shaped device filled with 38 mg of progesterone, the natural hormone. The hormone is released slowly in the uterus at the rate of 65 mcg daily. It has a direct local effect on the uterine lining, on the cervical mucus and possibly on the sperms. Because the hormone supply is gradually depleted, regular replacement of the device is necessary.

Another hormonal device LNG-20 (Mirena) is a T-shaped IUD releasing 20 mcg of levonorgestrel (a potent synthetic steroid); it has a low pregnancy rate (0.2 per 100 women) and less number of ectopic pregnancies (40). Long-term clinical experience with levonorgestrel releasing IUD has shown to be associated with lower menstrual blood loss and fewer days of bleeding than the copper devices. The levonorgestrel releasing IUD has an effective life of 10 years (40). The hormonal devices would be particularly valuable for women in developing countries in whom excess blood loss caused by inert devices have been shown to result in significant anaemia. But these devices are more expensive, to be introduced on a wide scale.
Mechanism of action of IUDs

At present, the most widely accepted view is that the IUD causes a foreign-body reaction in the uterus causing cellular and biochemical changes in the endometrium and uterine fluids, and it is believed that these changes impair the viability of the gamete and thus reduce its chances of fertilization, rather than its implantation.

Medicated IUDs produce other local effects that may contribute to their contraceptive action. Copper seems to enhance the cellular response in the endometrium (48). It also affects the enzymes in the uterus. By altering the biochemical composition of cervical mucus, copper ions may affect sperm motility, capacitation and survival (48).

Hormone-releasing devices increase the viscosity of the cervical mucus and thereby prevent sperm from entering the cervix. They also maintain high levels of progesterone in the endometrium and thus, relatively low levels of oestrogen, thereby sustaining an endometrium unfavourable to implantation (48).

Effectiveness

The IUD is one of the most effective reversible contraceptive methods. The “theoretical effectiveness” of IUD is less than that of oral and injectable hormonal contraceptives. But since IUDs have longer continuation rates than the hormonal pills or injections, the overall effectiveness of IUDs and oral contraceptives are about the same in family planning programmes (49).

Table 19 shows the rates of pregnancy, expulsion and removal of some of the IUDs. It can be seen from Table 19 that copper devices are more effective than the Lippes Loop in preventing pregnancy, with fewer expulsions. Studies have shown that the effectiveness of copper devices is directly related to the amount of copper surface area (usually this is 200 or 220 sq. mm.)

Change of IUD

Inert IUDs such as Lippes Loop may be left in place as long as required, if there are no side-effects. Copper devices cannot be used indefinitely because copper corrodes and mineral deposits build up on the copper affecting the release of copper ions. They have to be replaced periodically. The same applies to the hormone-releasing devices. This is an inherent disadvantage of medicated devices when they are used in large national family planning programmes.

The Cu-T-380A is approved for use for 10 years. However, the Cu-T-380A has been demonstrated to maintain its efficacy over at least 12 years of use. The Cu-T-200 is approved for 4 years and the Nova T for 5 years. The progesterone-releasing IUD must be replaced every year because the reservoir of progesterone is depleted in 12-18 months. The levonorgestrel IUD can be used for at least 7 years, and probably 10 years. The progesterone IUD has a slightly higher failure rate, but the levonorgestrel device that releases 15-20 μg levonorgestrel per day is as effective as the new copper IUDs (40).

Advantages

The IUD has many advantages: (a) simplicity, i.e., no complex procedures are involved in insertion; no hospitalization is required (b) insertion takes only a few minutes (c) once inserted IUD stays in place as long as required (d) inexpensive (e) contraceptive effect is reversible by removal of IUD (f) virtually free of systemic metabolic side-effects associated with hormonal pills (g) highest continuation rate, and (h) there is no need for the continual motivation required to take a pill daily or to use a barrier method consistently; only a single act of motivation is required. However, as with most contraceptive methods, the IUD can produce side-effects such as heavy menstruation and/or pain.

Contraindications

ABSOLUTE: (a) suspected pregnancy (b) pelvic inflammatory disease (c) vaginal bleeding of undiagnosed aetiology (d) cancer of the cervix, uterus or adnexia and other pelvic tumours (e) previous ectopic pregnancy (50).

RELATIVE: (a) anaemia (b) menorrhagia (c) history of PID since last pregnancy (d) purulent cervical discharge (e) distortions of the uterine cavity due to congenital malformations, fibroids (f) uninterested person (45).

The ideal IUD candidate

The Planned Parenthood Federation of America (PPFA) has described the ideal IUD candidate as a woman:
- who has borne at least one child
- has no history of pelvic disease
- has normal menstrual periods
- is willing to check the IUD tail
- has access to follow-up and treatment of potential problems, and
- is in a monogamous relationship.

The federation does not, however, rule out women who do not conform to this profile (51).

An important finding that has recently emerged is that the IUD is not a method of first choice for nulliparous women. They have more problems with IUD such as expulsions, low abdominal pain and pelvic infection, than other women. IUDs such as copper-T, which are smaller and more pliable are better suited to the small uterus of the nulliparous women, if they cannot use or accept alternative methods of contraception.

In 1985, the American College of Obstetricians and Gynaecologists stated that IUDs are “not recommended for women who have not had children or who have multiple partners, because of the risk of PID and possible infertility” (51).

Timing of insertion

Although the loop can be inserted at almost anytime during a woman's reproductive years (except during pregnancy), the most propitious time for loop insertion is
during menstruation or within 10 days of the beginning of a menstrual period (42). During this period, insertion is technically easy because the diameter of the cervical canal is greater at this time than during the secretory phase. The uterus is relaxed and myometrial contractions which might tend to cause expulsion are at a minimum (44). In addition, the risk that a woman is pregnant is remote at this time.

The IUD insertion can also be taken up during the first week after delivery before the woman leaves the hospital (“immediate postpartum insertion”). Special care is required with insertions during the first week after delivery because of the greater risk of perforation during this time. Furthermore, immediate postpartum insertion is associated with a high expulsion rate. A convenient time for loop insertion is 6–8 weeks after delivery (“post–puerperal insertion”). Postpuerperal insertion of an IUD has several advantages. It can be combined with the follow-up examination of the woman and her child. IUD insertion can also be taken up immediately after a legally induced first trimester abortion. But IUD insertion immediately after a second trimester abortion is not recommended (45). Since there is a risk of infection, most physicians still do not approve of an IUD insertion after an illegal abortion (45).

Follow-up

An important aspect of IUD insertion is follow-up which is sadly neglected. The objectives of the follow-up examination are: (a) to provide motivation and emotional support for the woman (b) to confirm the presence of the IUD, and (c) diagnose and treat any side-effect or complication (51). The IUD wearer should be examined after her first menstrual period, for the chances of loop expulsion are high during this period; and again after the third menstrual period to evaluate the problems of pain and bleeding; and thereafter at six-month or one-year intervals depending upon the facilities and the convenience of the patient.

The IUD wearer should be given the following instructions: (a) she should regularly check the threads or “tail” to be sure that the IUD is in the uterus; if she fails to locate the threads, she must consult the doctor (b) she should visit the clinic whenever she experiences any side-effects such as fever, pelvic pain and bleeding, and (c) if she misses a period, she must consult the doctor.

SIDE-EFFECTS AND COMPLICATIONS

1. Bleeding

The commonest complaint of women fitted with an IUD (inert or medicated) is increased vaginal bleeding. It accounts for 10–20 per cent of all IUD removals (51). The bleeding may take one or more of the following forms: greater volume of blood loss during menstruation, longer menstrual periods or mid-cycle bleeding (48). From the woman’s point of view, irregular bleeding constitutes a source of personal inconvenience; from a medical point of view, the concern is iron-deficiency anaemia. Usually bleeding or spotting between periods settles within 1–2 months (49). The patient who is experiencing the bleeding episodes should receive iron tablets (ferrous sulphate 200 mg, three times daily).

Studies have shown that the greatest blood loss is caused by the larger non-medicated devices. Copper devices seem to cause less average blood loss. Menstrual blood loss is consistently lower when hormone-releasing devices are used (45).

If the bleeding is heavy or persistent or if the patient develops anaemia despite the iron supplement, the IUD should be removed. Since there is often a direct relationship between the bleeding and the size and configuration of the IUD (50), a change of IUD from the Lippes Loop to one of copper devices is advised. In most women, removal of the device is rapidly followed by a return to the normal menstrual pattern. If an abnormal pattern persists, a full gynaecological examination is required to ensure that there is no pelvic pathology (45).

2. Pain

Pain is the second major side-effect leading to IUD removal, WHO estimates that 15–40 per cent of IUD removals appear to be for pain only (45). Pain may be experienced during IUD insertion and for a few days thereafter, as well as during menstruation (51). It may manifest itself in low backache, cramps in the lower abdomen and occasionally pain down the thighs. These symptoms usually disappear by the third month (49).

If during insertion, the pain is particularly severe, it is possible that the device may have been incorrectly placed in the uterus or there is a disparity in size between the device and the uterine cavity. Severe pain can also indicate a uterine perforation (45). Pain could also be due to infection. Pain is more commonly observed in nullipara and those who have not had a child for a number of years (52, 53).

Slight pain during insertion can be controlled by analgesics such as aspirin and codein. If pain is intolerable, the IUD should be removed. In place of a Lippes Loop, a copper device can be tried. If the woman decides not to have an IUD, another method of contraception should be prescribed.

3. Pelvic infection

Pelvic inflammatory disease (PID) is a collective term that includes acute, subacute and chronic conditions of the ovaries, tubes, uterus, connective tissue and pelvic peritoneum and is usually the result of infection (50). Studies suggest that IUD users are about 2 to 8 times more likely to develop PID than non-contraceptors (54). Risk associated with IUD use is greater among women who have a number of sexual partners (55) possibly because of greater potential for exposure to STDs. The greater risk of PID with IUD use may be due to introduction of bacteria into the uterus during IUD insertion. Recent work has focused on PID as being caused by organisms ascending the IUD tail from the lower genital tract to uterus and tubes (56). The organisms include Gardnerella, Anaerobic streptococci, Bacteroides, Caliform bacilli and Actinomycetes. The risk of PID appears to be the highest in the first few months after IUD insertion.

The clinical manifestations of PID are vaginal discharge, pelvic pain and tenderness, abnormal bleeding, chills and fever. In many cases, the infection may be asymptomatic or low grade. Even one or two episodes of PID can cause infertility permanently blocking the fallopian tubes. Therefore, young women should be fully counselled on the risks of PID before choosing an IUD.

When PID is diagnosed, it should be treated promptly with broad-spectrum antibiotics. Most clinicians recommend removing IUD if infection does not respond to antibiotics within 24–48 hours (48). The risk of PID calls for proper selection of cases for IUD insertion, better sterilization and insertion techniques, and modified devices without tails.
4. Uterine perforation

Many workers have reported uterine perforation by the IUD (57). The reported incidence ranges from 1:350 to 1:9000 insertions (57), depending upon the time of insertion, design of the IUD, technique of insertion and operator’s experience. In the hands of trained physicians, it should not be higher than 0.3 per cent (58). The device may migrate into the peritoneal cavity causing serious complications such as intestinal obstruction. Copper devices produce an intense tissue reaction leading to peritoneal adhesions. Perforations occur more frequently when insertions are performed between 48 hours and 6 weeks postpartum. Interestingly, the perforation may be completely asymptomatic and discovered only when searching for a missing IUD. The conclusive diagnosis of perforation is usually made by a pelvic X-ray. Evidence suggests that any IUD that has perforated the uterus should be removed because the risks of intra-abdominal inflammatory response leading to adhesions or perforation of organs within the abdominal cavity outweigh the risks associated with removal (51).

5. Pregnancy

Considering all IUDs together, the actual use failure rate in the first year is approximately 3 per cent (40). It differs in different types of IUDs. About 50 per cent of uterine pregnancies occurring with the device in situ end in a spontaneous abortion (51). Removal of the IUD in early pregnancy has been found to reduce this abortion rate by half. In women who continue the pregnancy with the device in situ, a 4-fold increase in the occurrence of premature births compared with other women has been reported (45).

The earlier teaching that pregnancy with an IUD in situ is not unsafe is no longer accepted. Pregnancy with an IUD should be regarded as a potential medical complication with the dangers of infection and spontaneous abortion. The options left open are (44):

(a) If the woman requests an induced abortion, this is legally available.

(b) If the woman wishes to continue with the pregnancy and the threads are visible, the device should be removed by gently pulling the threads.

(c) If the woman wishes to continue with the pregnancy and the threads are not visible, there should be careful examination for possible complications. If there are any signs of intrauterine infection and sepsis, evacuation of the uterus under broad-spectrum antibiotic cover is mandatory.

If the woman becomes pregnant with the IUD, she should be advised that only 25 per cent of pregnancies will have a successful outcome if the IUD is left in place.

6. Ectopic pregnancy

The possibility of ectopic pregnancy must be considered when an IUD user becomes pregnant. The ectopic pregnancy rate per 1000 women year in levonorgestrel IUD and Cu-T-380A is about 0.2 as compared to non-contraceptive users, where it is about 3-4.5. With progesteron IUD it is higher—about 6.8, because its action is limited to a local effect on endometrium. With levonorgestrel IUD the chances of ectopic pregnancy are less, because it is associated with a partial suppression of gonadotrophins with subsequent disruption of normal follicular growth and inhibition of ovulation in significant number of cycles (40).

Women using IUDs should be taught to recognize the symptoms of ectopic pregnancy — lower abdominal pain, dark and scanty vaginal bleeding or amenorrhoea. Women at high risk of ectopic pregnancy — because of previous PID, tubal pregnancy or other ectopic pregnancy — should not use an IUD if other methods are feasible (51).

7. Expulsion

Expulsion rates vary between 12–20 per cent (Table 19). Expulsion can be partial or complete. Partial expulsion is diagnosed on speculum examination by observing the stem of the IUD protruding through the cervix. Clinical skill, timing of insertion and the age and parity of the user all influence the likelihood of expulsion.

An expulsion usually occurs during the first few weeks following insertion or during menstruation. Expulsion is most common among young women, multiparous women and women who have a postpartum insertion. Expulsion rates are somewhat lower for copper than for inert devices. As many as 20 per cent of all expulsions go undetected. In general, expulsion in itself is not a serious problem, but if expulsion is unnoticed, pregnancy may occur.

8. Fertility after removal

Fertility does not seem to be impaired after removal of a device provided there has been no episode of PID, whilst the device was in situ (48). Over 70 per cent of previous IUD users conceive within one year of stopping use (51). It is now established that PID is a threat to woman’s fertility. There is no meaningful data available on the long-term use of IUD on subsequent fertility (45).

9. Cancer and teratogenesis

There is no evidence to date that IUD use increases cancer risks. Nor is there any evidence of developmental abnormality or congenital malformations among the offspring of either former users of IUDs or those who conceive with an IUD in situ (45).

10. Mortality

Mortality associated with IUD use is extremely rare and has been estimated to be one death per 100,000 woman-years of use, the deaths usually following complications such as septic spontaneous abortion or ectopic pregnancy (45). In fact, IUD is safer than oral contraceptives in this regard, particularly in older or high-risk patients (45).

Of all the available spacing methods of contraception, IUDs are among the most effective, with an average pregnancy rate after one year of about 3–5 per 100 typical users (51). In comparison with other methods, the IUD is a relatively inexpensive form of contraception, because of its long life. Unlike use of barrier methods, IUD use is independent of the time of intercourse. IUDs have a relatively high continuation rates. Invert devices, as well as those with copper lack the systemic metabolic effects associated with oral pills. Women who cannot tolerate the adverse effects of oral pills may find the IUD an acceptable alternative. It does not interfere with lactation. However, because of expulsion and possible side-effects like menstrual irregularities, IUDs should preferably be used in settings where follow-up facilities are available. Evidence to date shows that for a fully informed woman, the IUD can provide a satisfactory, highly effective, relatively low-risk method of contraception.
HORMONAL CONTRACEPTIVES

Hormonal contraceptives when properly used are the most effective spacing methods of contraception. Oral contraceptives of the combined type are almost 100 per cent effective in preventing pregnancy. They provide the best means of ensuring spacing between one childbirth and another. More than 65 million in the world are estimated to be taking the “pill” of which about 9.52 million are estimated to be in India.

Gonadal steroids

To physicians in general medicine, the term “steroid” refers to adrenocortical hormones, while to those in gynaecology, it implies gonadal steroids, i.e., oestrogens and progestogens.

a. Synthetic oestrogens: Two synthetic oestrogens are used in oral contraceptives. These are ethinyl-oestradiol and mestranol. Both are effective. In fact, mestranol is inactive until converted into ethinyl oestradiol in the liver (59).

b. Synthetic progestogens: These are classified into three groups – pregnanes, oestranes and gonanes. (i) Pregnanes: These include megestrol, chlormadinone and medroxy-progesterone acetate. The progesterone progestogens are now not recommended in oral contraceptives because of doubts raised by the occurrence of breast tumours in beagle dogs. (ii) Oestrones: These are also known as 19-nortestosterones, e.g., norethisterone, norethisterone acetate, lynestrenol, ethynodiol diacetate and norethynodrel. These are all metabolized to norethisterone before becoming active. For some women, oestranes are more acceptable than gonanes. (iii) Gonanes: The most favoured gonane is levonorgestrel (59).

Classification

Hormonal contraceptives currently in use and/or under study may be classified as follows:

A. Oral pills
   1. Combined pill
   2. Progestogen only pill (POP)
   3. Post-coital pill
   4. Once-a-month (long-acting) pill
   5. Male pill

B. Depot (slow release) formulations
   1. Injectables
   2. Subcutaneous implants
   3. Vaginal rings

A. ORAL PILLS

1. Combined pill

The combined pill is one of the major spacing methods of contraception. The “original pill” which entered into the market in the early 1960s contained 100–200 mcg of a synthetic oestrogen and 10 mg of a progestogen. Since then, a number of improvements have been made to reduce the undesirable side-effects of the pill by reducing the dose of both the oestrogen and progestogen. At the present time, most formulations of the combined pill contain no more than 30–35 mcg of a synthetic oestrogen, and 0.5 to 1.0 mg of a progestogen. The debate continues about the minimum effective dose of the progestogen in the pill which will produce the least metabolic disturbances.

The pill is given orally for 21 consecutive days beginning on the 5th day of the menstrual cycle (for a few preparations 20 or 22 days are advised), followed by a break of 7 days during which period menstruation occurs. When the bleeding occurs, this is considered the first day of the next cycle. The bleeding which occurs is not like normal menstruation, but is an episode of uterine bleeding from an incompletely formed endometrium caused by the withdrawal of exogenous hormones. Therefore it is called “withdrawal bleeding” rather than menstruation. Further, the loss of blood which occurs is about half that occurring in a woman having ovulatory cycle. If bleeding does not occur, the woman is instructed to start the second cycle one week after the preceding one. Ordinarily, the woman “menstruates” after the second course of pill intake.

The pill should be taken everyday at a fixed time, preferably before going to bed at night. The first course should be started strictly on the 5th day of the menstrual period, as any deviation in this respect may not prevent pregnancy. If the user forgets to take a pill, she should take it as soon as she remembers, and that she should take the next day’s pill at the usual time.

Types of pills

The Department of Family Welfare, in the Ministry of Health and Family Welfare, Government of India has made available 2 types of low-dose oral pills under the brand names of MALA-N and MALA-D. It contains Levonorgestrel 0.15 mg and Ethinyl estradiol 0.03 mg. Mala-D in a package of 28 pills (21 of oral contraceptive pills and 7 brown film coated 60 mg ferrous fumarate tablets) is made available to the consumer under social marketing at a price of Rs. 3 per packet. Mala-N is supplied free of cost through all PHCs, urban family welfare centres, etc. Some of the combined pills are as shown in Table 20.

2. Progestogen-only pill (POP)

This pill is commonly referred to as "minipill" or "micropill". It contains only progestogen, which is given in small doses throughout the cycle. The commonly used progestogens are norethisterone and levonorgestrel.

The progestogen-only pills never gained widespread use because of poor cycle control and an increased pregnancy rate (60). However, they have a definite place in modern-day contraception. They could be prescribed to older women for whom the combined pill is contraindicated because of cardiovascular risks. They may also be considered in young women with risk factors for neoplasia (61). The evidence that the progestogens may lower the high-density lipoproteins may be of some concern.

3. Post-coital contraception

Post-coital (or "morning after") contraception is recommended within 72 hours of an unprotected intercourse. Two methods are available:

(a) IUD : The simplest technique is to insert an IUD, if acceptable, especially a copper device within 5 days

(b) Hormonal : More often a hormonal method may be preferable. In India Levonorgestrel 0.75 mg tablet is approved for emergency contraception. It is used as one tablet of 0.75 mg within 72 hours of unprotected sex and the 2nd tablet after 12 hours of 1st dose.

or

Two oral contraceptive pills containing 50 mcg of ethinyl estradiol within 72 hours after intercourse, and the same dose after 12 hours

or

Four oral contraceptive pills containing 30 or 35 mcg of ethinyl estradiol within 72 hours and 4 tablets after 12 hours

or

Mifepristone 10 mg once within 72 hours.

Post-coital contraception is advocated as an emergency method; for example, after unprotected intercourse, rape or contraceptive failure. Opinion is divided about the effect on fertility unless she intends to have an abortion, if the method fails. There is no evidence that foetal abnormalities will occur. But some doubts remain (62).

4. Once-a—month (long-acting) pill

Experiments with once-a—month oral pill in which quinestrol, a long-acting oestrogen is given in combination with a short-acting progestogen, have been disappointing (63). The pregnancy rate is too high to be acceptable. In addition, bleeding tends to be irregular.

5. Male pill

The search for a male contraceptive began in 1950 (64). Research is following 4 main lines of approach (a) preventing spermatogenesis (b) interfering with sperm storage and maturation (c) preventing sperm transport in the vas, and (d) affecting constituents of the seminal fluid. Most of the research is concentrated on interference with spermatogenesis. An ideal male contraceptive would decrease sperm count while leaving testosterone at normal levels. But hormones that suppress sperm production tend to lower testosterone and affect potency and libido.

A male pill made of gossypol – a derivative of cotton-seed oil, has been very much in the news. It is effective in producing azoospermia or severe oligospermia, but as many as 10 per cent of men may be permanently azoospermic after taking it for 6 months. Further gossypol could be toxic. Animal studies show a narrow margin between effective and toxic doses. At present it does not seem that gossypol will ever be widely used as a male contraceptive (65).

MODE OF ACTION OF ORAL PILLS

The mechanism of action of the combined oral pill is to prevent the release of the ovum from the ovary. This is achieved by blocking the pituitary secretion of gonadotropin that is necessary for ovulation to occur. Progestogen—only preparations render the cervical mucus thick and scanty and thereby inhibit sperm penetration. Progestogens also inhibit tubal motility and delay the transport of the sperm and of the ovum to the uterine cavity (63).

EFFECTIVENESS

Taken according to the prescribed regimen, oral contraceptives of the combined type are almost 100 per cent effective in preventing pregnancy (50). Some women do not take the pill regularly, so the actual rate is lower. In developed countries, the annual pregnancy rate is less than 1 per cent but in many other countries, the pregnancy rate is considerably higher (63).

Under clinical trial conditions, the effectiveness of progestogen—only pills is almost as good as that of the combination products. However, in large family planning programmes, the effectiveness and continuation rates are usually lower than in clinical trials. The effectiveness may also be affected by certain drugs such as rifampicin, phenobarbital and ampicillin (63).

RISKS AND BENEFITS

Historically oral contraceptives were introduced in the early 1960s. During the first decade of their use, investigations focused on the benefit of pregnancy prevention and risk of abnormal cycle bleeding. During the 1970s, following their widespread use it became apparent that the oral contraceptives had some adverse effects principally on the cardiovascular system (e.g., myocardial infarction, deep vein thrombosis, etc.) and that these effects were associated with the oestrogen component of the pill. This led to a reduction of the oestrogen content of the pill until the current 30–35 mcg oral pills were developed. Until 1980, there was little mention of the untoward effects of progestogens.

As we entered the third decade of oral pill use in 1980s, more information about the hazards and benefits of the pill were available from two large British prospective studies – the Royal College of General Practitioners’ study and the Oxford University Family Planning Association’s study, both of which started in 1968 (65, 66, 67). This section summarizes the risks and benefits of the pill as of date.

a. Adverse effects

1. Cardiovascular effects

Data from the earlier case control studies (68, 69) and the Oral Contraceptive Study of the RCGP (68) and the Oxford
Study in UK (66, 67) provided conclusive evidence that the use of the combined pill was associated with an excess mortality. Women who had used the pill were reported to have a 40 per cent higher death rate than women who had never taken the pill. Virtually, all the excess mortality was due to cardiovascular causes, that is myocardial infarction, cerebral thrombosis and venous thrombosis, with or without pulmonary embolus (70, 71). The risk increased substantially with age and cigarette smoking (Table 21). The evidence was convincing that the cardiovascular complications were positively associated with the oestrogen content of the pill.

Source: (72)

The above findings led to the progressive reduction of the oestrogen content to the minimum levels necessary to maintain contraceptive effect. Instead of this reduction, it became clear by 1980 that some of the untoward vascular effects (e.g., hypertension) persisted, in addition to metabolic effects which are attributed to the progestogen content of the pill. It became clear that progestogen levels must also be minimal to avoid the complications of pill use.

2. Carcinogenesis

A review prepared by WHO (73) concluded that there was no clear evidence of a relationship, either positive or negative, between the use of combined pill and the risk of any form of cancer. However, the WHO Multicentre case-control study on the possible association between the use of hormonal contraceptives and neoplasia indicated a trend towards increased risk of cervical cancer with increasing duration of use of oral contraceptives; this finding is being further explored (74).

3. Metabolic effects

A great deal of attention has been focused recently on the metabolic effects induced by oral contraceptives. These have included the elevation of blood pressure, the alteration in serum lipids with a particular effect on decreasing high-density lipoproteins, blood clotting and the ability to modify carbohydrate metabolism with the resultant elevations of blood glucose and plasma insulin (75). These effects are positively related to the dose of the progestogen component (76). Family planning specialists have voiced a growing concern that the adverse effects associated with oral contraceptives could be a potential long-range problem for the users in that they may accelerate atherogenesis and result in clinical problems such as myocardial infarction and stroke.

4. Other adverse effects

(i) Liver disorders: The use of the pill may lead to hepatocellular adenoma and gall bladder disease. Cholestatic jaundice can occur in some pill users.

(ii) Lactation: Preparations containing a relatively high amount of oestrogen adversely affect the quantity and constituents of breast milk (74), and less frequently cause premature cessation of lactation. In a WHO study (74) users of the combined pill experienced a 42 per cent decline in milk volume after 18 weeks, compared with a decline of 12 per cent for users of progestogen-only minipills and 0.16 per cent for controls using non-hormonal preparations. Women taking oral contraceptives, no matter what type, excrete small quantities of hormones in their breast milk, but little is known about the long-term impact, if any, on the child (71). (iii) Subsequent fertility: In general, oral contraceptive use seems to be followed by a slight delay in conception (77). The proportion of women becoming pregnant within 2 months of discontinuing the pill may range from 15-35 per cent (78). It is not known whether the prolonged use of the pill beyond 5-10 years affects subsequent fertility. (iv) Ectopic pregnancies: These are more likely to occur in women taking progestogen-only pills, but not in those taking combined pills. (v) Foetal development: Several reports have suggested that oral pills taken inadvertently during (or even just before) pregnancy might increase the incidence of birth defects of the foetus, but this is not yet substantiated (79).

5. Common unwanted effects

(i) Breast tenderness: Breast tenderness, fullness and discomfort have been observed in women taking oral pills. Breast engorgement and fullness are said to be dependent on progestogen; pain and tenderness are attributed to oestrogen. (ii) Weight gain: About 25 per cent of users complain of weight gain. It is usually less than 2 kg, and occurs during the first 6 months of use. This is attributed to water retention, in which case restriction of salt intake is usually effective. (iii) Headache and migraine: Migraine may be aggravated or triggered by the pill. Women, whose migraine requires treatment with vasoconstrictors such as ergotamine, should not take oral pills. (iv) Bleeding disturbances: A small minority of women using oral contraceptives may complain of break-through bleeding or spotting in the early cycles. A few women may not have a withdrawal bleeding at the end of a cycle. Women should be forewarned of these possibilities.

b. Beneficial effects

The single most significant benefit of the pill is its almost 100 per cent effectiveness in preventing pregnancy and thereby removing anxiety about the risk of unplanned pregnancy. Apart from this, the pill has a number of non-contraceptive health benefits (80). Both the Royal College of General Practitioners' and the Oxford Family Planning Association's long-term prospective studies of pill use in Britain have shown that using the pill may give protection against at least 6 diseases: benign breast disorders including fibrocystic disease and fibroadenoma, ovarian cysts, iron-deficiency anaemia, pelvic inflammatory disease, ectopic pregnancy and ovarian cancer.
**Contraindications**

(a) **Absolute**: Cancer of the breast and genitals; liver disease; previous or present history of thromboembolism; cardiac abnormalities; congenital hyperlipidaemias; undiagnosed abnormal uterine bleeding.

(b) **Special problems requiring medical surveillance**: Age over 40 years; smoking and age over 35 years; mild hypertension; chronic renal disease; epilepsy; migraine; nursing mothers in the first 6 months; diabetes mellitus; gall bladder disease; history of infrequent bleeding, amenorrhoea, etc. (63).

**Duration of use**

The pill should be used primarily for spacing pregnancies in younger women. Those over 35 years should go in for other forms of contraception. Beyond 40 years of age, the pill is not to be prescribed or continued because of the sharp increase in the risk of cardiovascular complications (63).

**Medical supervision** (81)

Women taking oral contraceptives should be advised annual medical examinations. An examination before prescribing oral pills is required (a) to identify those with contraindications, and (b) those with special problems that require medical intervention or supervision. A check-list (Table 22) has been developed for screening women who can be given oral pills by the health workers.

**Table 22**

**Instructions**: If all the above are negative, the woman may be given oral contraceptives. If any are positive, she must first be seen by a doctor.

**B. DEPOT FORMULATIONS**

The need for depot formulations which are highly effective, reversible, long-acting and oestrogen-free for spacing pregnancies in which a single administration suffices for several months or years cannot be stressed. The injectable contraceptives, subdermal implants and vaginal rings come in this category.

1. **Injectable contraceptives**

There are two types of injectable contraceptives. Progestogen-only injectables and the newer once-a-month combined injectables. The formulation and injection schedules of injectable contraceptives are as shown in Table 23.

A. **PROGESTOGEN-ONLY INJECTABLES**

Thus far, only two injectable hormonal contraceptives—both based on progestogen—have been found suitable. They offer more reliable protection against unwanted pregnancies than the older barrier techniques. These are:

a. **DMPA (Depot-medroxyprogesterone acetate)**

b. **NET-EN (Norethisterone enantate)**

c. **DMPA-SC**

**a. DMPA** (82)

Depot-medroxyprogesterone acetate (DMPA or Depo-provera) has been in use since 1960. The standard dose is an intramuscular injection of 150 mg every 3 months. It gives protection against pregnancy in 99 per cent of women for at least 3 months. It exerts its contraceptive effect primarily by suppression of ovulation. However, it also has an indirect effect on the endometrium and direct action on the fallopian tubes and on the production of cervical mucus, all of which may play a role in reducing fertility. DMPA has been found to be a safe, effective and acceptable contraceptive which requires a minimum of motivation or none at all. Another advantage is that it does not affect lactation. Therefore in the experience of several countries, DMPA has proved acceptable during the postpartum period as a means of spacing pregnancies. However, the side-effects of DMPA (viz. weight increase, irregular menstrual bleeding and prolonged infertility after its use) are disadvantages limiting the age groups for which the drug could regularly be used. As now practiced in a number of countries, this contraceptive should find good use among multiparae of age over 35 years who have already completed their families.

**b. NET-EN**

Norethisterone enantate (NET-EN) has been in use since 1966. However, it has been less extensively used than DMPA. It is given intramuscularly in a dose of 200 mg every 60 days. Contraceptive action appears to include inhibition of ovulation, and progestogenic effects on cervical mucus. A slightly higher (0.4) pregnancy rate (failure rate) has been reported as compared to DMPA.

**Administration**

The initial injection of both DMPA and NET-EN should be given during the first 5 days of the menstrual period. This timing is very important to rule out the possibility of pregnancy. Both are given by deep intramuscular injection into the gluteus maximus. The injection site should never be massaged following injections. (83). Although compliance
HORMONAL CONTRACEPTIVES

* Also called monthly injectables

The U.S. Food and Drug Administration approved Lunelle but it is not currently available in the United States.

Source: (82)

with regular injection intervals should be encouraged, both DMPA and Net-EN may be given two weeks early or two weeks late (84).

c. DMPA-SC 104 mg (82)

A new lower-dose formulation of DMPA, depo-subQ provera 104 (also called DMPA-SC), is injected under the skin rather than in the muscle. It contains 104 mg of DMPA rather than the 150 mg in the intramuscular formulation. Like the intramuscular formulation, DMPA-SC is given at 3-month intervals.

DMPA-SC is just as effective as the formulation injected into the muscle, and the patterns of bleeding changes and amount of weight gain are similar.

Injections of DMPA-SC are given in the upper thigh or abdomen. DMPA-SC should not be injected intramuscularly, and the intramuscular formulation should not be injected subcutaneously. The intramuscular formulation cannot be diluted to make the lower-dose subcutaneous formulation.

Side-effects

Both DMPA and NET-EN have similar side effects, the most common being disruption of the normal menstrual cycle, manifested by episodes of unpredictable bleeding, at times prolonged and at other times excessive. In addition, many women using DMPA or NET-EN may become amenorrhoeic. The unpredictable bleeding may be very inconvenient to the user; and amenorrhoea can be alarming, causing anxiety. Studies showed that women discontinuing DMPA became pregnant some 5.5 months (average) after the treatment period. At 2 years, more than 90 per cent of previous users became pregnant (83). A study is in progress in India to examine the return of fertility among women who discontinued NET-EN. The potential long-term effects of DMPA and NET-EN are not yet known.

Contraindications

These include cancer of the breast; all genital cancers; undiagnosed abnormal uterine bleeding; and a suspected malignancy. Women usually should not start using a progestin-only injectable if they have high blood pressure (systolic ≥ 160 mm Hg or diastolic ≥ 100), certain conditions of the heart, blood vessels, or liver including history of stroke or heart attack and current deep vein thrombosis. Also, a woman breast-feeding a baby less than 6 weeks old should not use progestin-only injectables (82).

The particular advantage of DMPA and NET-EN is that they are highly effective, long-lasting and reversible contraceptives. Check-lists have been developed for auxiliaries primarily for the screening of women who can be given injectable contraceptives without being examined by the physician; they can also be utilized in follow-up visits.

B. COMBINED INJECTABLE CONTRACEPTIVES

These injectables contain a progestogen and an oestrogen. They are given at monthly intervals, plus or minus three days. Combined injectable contraceptives act mainly by suppression of ovulation. The cervical mucus is affected, mainly by progestogen, and becomes an obstacle to sperm penetration. Changes are also produced in endometrium which makes it unfavourable for implantation if fertilization occurs, which is extremely unlikely.

In clinical trials, Cyclofem-Cycloprovera and Mesigyna have both been found to be highly effective with 12 month failure rates of 0.2 per cent or less for Cyclofem Cycloprovera and 0.4 per cent for Mesigyna. The side-effects are similar to progestogen only injectables, but are much less. Data on return to ovulation and fertility are limited.

The contraindications are confirmed or suspected pregnancy; past or present evidence of thromboembolic disorders; cerebrovascular or coronary artery disease; focal migraine; malignancy of the breast; and diabetes with
lasting about 7 minutes, followed by cyclic contractions
solution (or 2.5-5 mg pellet) of prostaglandin F2. Within a
sedation, the uterus responds with a sustained contraction
continuing for 3-4 hours. The bleeding starts and continues
for 7-8 days (87).

Few minutes of the prostaglandin impact, performed under
prostaglandin balance by intrauterine application of 1-5 mg

Menstrual induction

This is based on disturbing the normal progesterone-
prostaglandin balance by intrauterine application of 1-5 mg
solution (or 2.5-5 mg pellet) of prostaglandin F2. Within a
few minutes of the prostaglandin impact, performed under
sedation, the uterus responds with a sustained contraction
lasting about 7 minutes, followed by cyclic contractions
continuing for 3-4 hours. The bleeding starts and continues
for 7-8 days (87).

Oral abortifacient

Mifepristone (RU 486) in combination with misoprostol is
95 per cent successful in terminating pregnancies of upto
9 weeks duration with minimum complications. The
commonly used regimen is mifepristone 200 mg orally on
day 1, followed by misoprostol 800 mcg vaginally either
immediately or within 6-8 hours. Commercially it comes as
MTP kit having combipack tablets of mifepristone 200 mg
one tablet and misoprostol 200 mcg 4 tablets (800 mcg).

The other regimen is a dose of mifepristone 600 mg on day
one, followed by 400 mcg orally of misoprostol on day three.

The patient should return for a follow-up visit
approximately 14 days after the administration of
mifepristone to confirm by clinical examination or ultra-
sonographic scan that a complete termination of pregnancy
has occurred. Patients who have an ongoing pregnancy at
this visit have a risk of foetal malformation resulting from the
treatment. Surgical termination is recommended to manage
medical abortion treatment failures.

Contraindications

Administration of mifepristone and misoprostol is
contraindicated in following conditions: (1) History of
allergy or known hypersensitivity to mifepristone,
misoprostol or other prostaglandin; (2) Confirmed or
suspected ectopic pregnancy or undiagnosed adnexal mass;
(3) IUD in place; (4) Chronic adrenal failure;
(5) Haemorrhagic disorder or concurrent anticoagulant
therapy; (6) Inherited porphyria; and (7) If a patient does
not have adequate access to medical facilities equipped to
provide emergency treatment of incomplete abortion and
blood transfusion.

Abortion

Abortion is theoretically defined as termination of
pregnancy before the foetus becomes viable (capable of
living independently). This has been fixed administratively
at 28 weeks, when the foetus weighs approximately 1000 g.
Abortion is sought by women for a variety of reasons
including birth control. In fact, in some countries (e.g.,
Hungary) the legal abortions exceed live births.

Abortions are usually categorized as spontaneous and
induced. Spontaneous abortions occur once in every
15 pregnancies (89). They may be considered "Nature's
method of birth control". Induced abortions, on the other
hand, are deliberately induced - they may be legal or illegal.
Illegal abortions are hazardous; they are usually the last
resort of women determined to end their pregnancies at the
risk of their own lives.

Abortion hazards

Between 2010-2014, on an average, 56 million induced
(safe and unsafe) abortions occurred worldwide each year.
There were 35 induced abortions per 1000 women aged
between 15–44 years, 25% of all pregnancies ended in an
induced abortion. The rate of abortion was higher in
developing regions than in developed world. About 25 million
unsafe abortions were estimated to have taken place
worldwide each year, almost all in developing world. Among
these, 8 million were carried out in the least safe or dangerous
conditions. Over half of all estimated unsafe abortions globally
were in Asia. 3 out of 4 abortions that occurred in Africa and
Latin America were unsafe. Each year between 4.7 per cent to
13.2 per cent of maternal deaths can be attributed to unsafe
abortion. Around 7 million women are hospitalized each year in developing countries as a result of unsafe abortion.

Abortions are safe if they are done with a method recommended by WHO that is appropriate to the pregnancy duration and if the person providing abortion is trained. Unsafe abortion occurs when a pregnancy is terminated either by a person lacking the necessary skills or in an environment that does not conform to minimal medical standards, or both. The people, skills and medical standards considered safe in the provision of induced abortion are different for medical abortion (which is performed by drugs alone and/or surgical abortion) and that which is performed with a manual or electric aspirator. In developed regions it is estimated that 30 women die for every 100,000 unsafe abortions. This number rises to 220 deaths, per 100,000 unsafe abortions in developing regions and 520 deaths in sub-Saharan Africa (90).

In India an ICMR study documented that the rates of safe (legal) and unsafe (illegal) abortion were 6.1 and 13.5 per 1000 pregnancies respectively. It is evident that perhaps two thirds of all abortions take place outside authorized health service by unauthorized and often unskilled persons (91).

The EARLY COMPLICATIONS of abortion include haemorrhage, shock, sepsis; uterine perforation, cervical injury, thromboembolism and anaesthetic and psychiatric complications. The LATE SEQUELAE include infertility, ectopic gestation, increased risk of spontaneous abortion and reduced birth weight.

Data indicates that the seventh and eighth week of gestation is the optimal time for termination of pregnancy (92). Studies indicate that the risk of death is 7 times higher for women who wait until the second trimester to terminate pregnancy. The Indian Law (MTP Act, 1971) allows abortion only up to 20 weeks of pregnancy.

Legalization of abortion

During the last 25 years there have been gradual liberalization of abortion laws throughout the world. Until 1971, abortions in India were governed exclusively by the Indian Penal Code 1860 and the Code of Criminal Procedure 1898, and were considered a crime except when performed to save the life of a pregnant woman. The Medical Termination of Pregnancy Act was passed by the Indian Parliament in 1971 and came into force from April 1, 1972 (except in Jammu and Kashmir, where it came into effect from November 1, 1976). Implementing rules and regulations initially written in 1971 were revised again in 1992 (95). The Medical Termination of Pregnancy Act is a health care measure which helps to reduce maternal morbidity and mortality resulting from illegal abortions. It also affords an opportunity for motivating such women to adopt some form of contraception.

THE MEDICAL TERMINATION OF PREGNANCY ACT 1971

The Medical Termination of Pregnancy Act, 1971 lays down:

1. The conditions under which a pregnancy can be terminated.
2. The person or persons who can perform such terminations, and
3. The place where such terminations can be performed.

There are 5 conditions that have been identified in the Act:

a. Medical – where continuation of the pregnancy might endanger the mother’s life or cause grave injury to her physical or mental health.
b. Eugenic – where there is substantial risk of the child being born with serious handicaps due to physical or mental abnormalities.
c. Humanitarian – where pregnancy is the result of rape.
d. Socio-economic – where actual or reasonably foreseeable environments (whether social or economic) could lead to risk of injury to the health of the mother, and
e. Failure of contraceptive devices – The anguish caused by an unwanted pregnancy resulting from a failure of any contraceptive device or method can be presumed to constitute a grave mental injury to the health of the mother. This condition is a unique feature of the Indian law and virtually allows abortion on request, in view of the difficulty of proving that a pregnancy was not caused by failure of contraception.

The written consent of the guardian is necessary before performing abortion in women under 18 years of age, and in lunatics even if they are older than 18 years.

2. The person or persons who can perform abortion

The Act provides safeguards to the mother by authorizing only a Registered Medical Practitioner having experience in gynaecology and obstetrics to perform abortion where the length of pregnancy does not exceed 12 weeks. However, where the pregnancy exceeds 12 weeks and is not more than 20 weeks, the opinion of two Registered Medical Practitioners is necessary to terminate the pregnancy.

3. Where abortion can be done

The Act stipulates that no termination of pregnancy shall be made at any place other than a hospital established or maintained by Government or a place approved for the purpose of this Act by Government.

Abortion services are provided in hospitals in strict confidence. The name of the abortion seeker is kept confidential, since abortion has been treated statutorily as a personal matter.

MTP RULES (1975)

Rules and Regulations framed initially were altered in October 1975 to eliminate time-consuming procedures involved in MTP and to make services more readily available. These changes have occurred in 3 administrative areas (93, 94)

1. Approval by Board

Under the new rules, the Chief Medical Officer of the district is empowered to certify that a doctor has the necessary training in gynaecology and obstetrics to do abortions. The procedure of doctors applying to Certification Boards was removed.

2. Qualification required to do abortion

The new rules allow for registered medical practitioners to qualify through on the spot training:

"If he has assisted a RMP in the performance of 25 cases of medical termination of pregnancy in an approved institution".
The doctor may also qualify to do MTPs under the new rules if he has one or more of the following qualifications which are similar to the old rules:

- (a) 6 months housemanship in obstetrics and gynaecology.
- (b) A postgraduate qualification in OBG.
- (c) 3 years of practice in OBG for those doctors registered before the 1971 MTP Act was passed.
- (d) 1 year of practice in OBG for those doctors registered on or after the date of commencement of the Act.

3. The place where abortion is performed

Under the new rules, non-governmental institutions may also take up abortions provided they obtain a licence from the Chief Medical Officer of the district, thus eliminating the requirement of private clinics obtaining a Board licence.

Impact of liberalization of abortion

Although abortion has been greatly liberalized, the annual number of legal abortions are about 6.1 per 1000 pregnancies, whereas the illegal abortions performed in the country are about 13.5 per 1000 pregnancies. In other words, illegal abortions are still rife although it is now more than 45 years since MTP Act was promulgated.

An amendment to the MTP Act in the year 2003 includes decentralization of power for approval of places as MTP centres, from state to district level with the aim of enlarging the network of safe MTP centres, and MTP service providers. The strategy at the community level is: (a) spread awareness regarding safe MTP in the community and the availability of services thereof; (b) Enhance access to confidential counselling for safe MTP; train ANMs, AWWs, and link workers ASHAs to provide such counselling; and (c) Promote post-abortion care through ANMs, AWWs, link workers ASHAs while maintaining confidentiality. At the facility level the strategy is: (1) To provide manual Vacuum Aspiration facility at all CHCs and at least 50 per cent of PHCs that are being strengthened for 24 hour deliveries; (2) Provide comprehensive and high quality MTP services at all FRUs; and (3) Encourage private and NGO sectors to establish quality MTP services (96).

Repeated abortion is not conducive to the health of the mother. It has to be ensured that abortion does not replace the traditional methods of birth control. The numerous abortion hazards which are inherent should serve as a warning that abortions under the best of circumstances can never be as safe as efficient contraception.

**MISCELLANEOUS**

1. Abstinence

The only method of birth control which is completely effective is complete sexual abstinence. It is sound in theory: in practice, an oversimplification. It amounts to repression of a natural force and is liable to manifest itself in other directions such as temperamental changes and even nervous breakdown. Therefore, it can hardly be considered as a method of contraception to be advocated to the masses.

2. Coitus interruptus

This is the oldest method of voluntary fertility control. It involves no cost or appliances. It continues to be a widely practised method. The male withdraws before ejaculation, and thereby tries to prevent deposition of semen into the vagina. Some couples are able to practise this method successfully, while others find it difficult to manage. The chief drawback of this method is that the pre-coital secretion of the male may contain sperm, and even a drop of semen is sufficient to cause pregnancy. Further, the slightest mistake in timing the withdrawal may lead to the deposition of a certain amount of semen. Therefore, the failure rate with this method may be as high as 25 per cent.

Hitherto, the alleged side-effects (e.g., pelvic congestion, vaginismus, anxiety neurosis) were highly magnified. Today, expert opinion is changing in this respect. If the couple prefers it, there should be no objection to its use. It is better than using no family planning method at all. It is conceded that coitus interruptus along with abstinence and abortion played a major role in reducing birth rates in the developed world during the 18th and 19th centuries (44).

3. Safe period (rhythm method)

This is also known as the “calendar method” first described by Ogino in 1930. The method is based on the fact that ovulation occurs from 12 to 16 days before the onset of menstruation (see Fig. 8). The days on which conception is likely to occur are calculated as follows:

**Fig. 8**

Safe period in a 28-day cycle

The shortest cycle minus 18 days gives the first day of the fertile period. The longest cycle minus 10 days gives the last day of the fertile period. For example, if a woman's menstrual cycle varies from 26 to 31 days, the fertile period during which she should not have intercourse would be from the 8th day to the 21st day of the menstrual cycle, counting day one as the first day of the menstrual period. Fig. 8 shows the fertile period and the safe period in a 28-day cycle.

However, where such calculations are not possible, the couple can be advised to avoid intercourse from the 8th to the 22nd day of the menstrual cycle, counting from the first day of the menstrual period (95).

The drawbacks of the calendar method are: (a) a woman's menstrual cycles are not always regular. If the cycles are irregular, it is difficult to predict the safe period (b) it is only possible for this method to be used by educated and responsible couples with a high degree of motivation and cooperation (c) compulsory abstinence of sexual intercourse for nearly one half of every month — what may be called “programmed sex” (d) this method is not...
applicable during the postnatal period, and (e) a high failure rate of 9 per 100 woman-years (39). The failures are due to wrong calculations, inability to follow calculations, irregular use and “taking chances”.

Two medical complications have been reported to result from the use of safe period; ectopic pregnancies and embryonic abnormalities. Ectopic pregnancies may follow conception late in the menstrual cycle and displacement of the ovum; embryonic abnormalities may result from conception involving either an over-aged sperm or over-aged ovum. If this is correct, the safe period may not be an absolutely safe period (97).

4. Natural family planning methods

The term “natural family planning” is applied to three methods: (a) basal body temperature (BBT) method (b) cervical mucus method, and (c) symptothermic method. The principle is the same as in the calendar method, but here the woman employs self-recognition of certain physiological signs and symptoms associated with ovulation as an aid to ascertain when the fertile period begins. For avoiding pregnancy, couples abstain from sexual intercourse during the fertile phase of the menstrual cycle; they totally desist from using drugs and contraceptive devices. This is the essence of natural family planning.

(a) Basal body temperature method (BBT)

The BBT method depends upon the identification of a specific physiological event – the rise of BBT at the time of ovulation, as a result of an increase in the production of progesterone. The rise of temperature is very small, 0.3 to 0.5 degree C. When no ovulation occurs (e.g., as after menarche, during lactation) the body temperature does not rise. The temperature is measured preferably before getting out of bed in the morning. The BBT method is reliable if intercourse is restricted to the post-ovulatory infertile period, commencing 3 days after the ovulatory temperature rise and continuing up to the beginning of menstruation. The major drawback of this method is that abstinence is necessary for the entire pre-ovulatory period. Therefore, few couples now use the temperature method alone (98).

(b) Cervical mucus method

This is also known as “billings method” or “ovulation method”. This method is based on the observation of changes in the characteristics of cervical mucus. At the time of ovulation, cervical mucus becomes watery clear resembling raw egg white, smooth, slippery and profuse. After ovulation, under the influence of progesterone, the mucus thickens and lessens in quantity. It is recommended that the woman uses a tissue paper to wipe the inside of vagina to assess the quantity and characteristics of mucus. To practice this method the woman should be able to distinguish between different types of mucus. This method requires a high degree of motivation than most other methods. The appeal and appropriateness of this method in developing countries such as India, especially among lay people, is dubious.

(c) Symptothermic method

This method combines the temperature, cervical mucus and calendar techniques for identifying the fertile period. If the woman cannot clearly interpret one sign, she can “double check” her interpretation with another. Therefore, this method is more effective than the “Billings method”.

To sum up, natural family planning demands discipline and understanding of sexuality. It is not meant for everybody. The educational component is more important with this approach than with other methods. The opinion of the Advisory Group to WHO’s Special Programme of Research in Human Reproduction is that the current natural family planning methods have very little application particularly in developing countries (99).

5. Breast-feeding

Field and laboratory investigations have confirmed the traditional belief that lactation prolongs postpartum amenorrhoea and provides some degree of protection against pregnancy (100). No more than 5–10 per cent of women conceive during lactational amenorrhoea, and even this risk exists only during the month preceding the resumption of menstruation (101). However, once menstruation returns, continued lactation no longer offers any protection against pregnancy (102). By and large, by 6 months after childbirth, about 20–50 per cent of women are menstruating and are in need of contraception (103).

6. Birth control vaccine

Several immunological approaches for men and women are being investigated. The most advanced research involves immunization with a vaccine prepared from beta sub-unit of human chorionic gonadotropin (hCG), a hormone produced in early pregnancy. Immunization with hCG would block continuation of the pregnancy. Antibodies appeared in about 4–6 weeks and reached maximum after about 5 months and slowly declined reaching zero levels after a period ranging from 6-11 months. The immunity can be boosted by a second injection. Two types of pregnancy vaccines employing variants of the beta sub-unit of hCG are now about to go into clinical trial (51). Research on birth control vaccines continues. The uncertainties are great (86).

TERMINAL METHODS

(Sterilization)

Voluntary sterilization is a well-established contraceptive procedure for couples desiring no more children. Currently female sterilizations account for about 85 per cent and male sterilizations for 10–15 per cent of all sterilizations in India (104), despite the fact that male sterilization is simpler, safer and cheaper than female sterilization.

Sterilization offers many advantages over other contraceptive methods – it is a one-time method; it does not require sustained motivation of the user for its effectiveness; provides the most effective protection against pregnancy; the risk of complications is small if the procedure is performed according to accepted medical standards; and it is most cost-effective. It has been estimated that each procedure averts 1.5 to 2.5 births per woman (105).

Guidelines for sterilization

Sterilization services are provided free of charge in Government institutions. Guidelines have been issued from time to time by the Government covering various aspects of sterilization. These are (106, 107):

a. The age of the husband should not ordinarily be less than 25 years nor should it be over 50 years.

b. The age of the wife should not be less than 20 years or more than 45 years.
Male sterilization (108, 109)

Male sterilization or vasectomy being a comparatively simple operation can be performed even in primary health centres by trained doctors under local anaesthesia. When carried out under strict aseptic technique, it should have no risk of mortality. In vasectomy, it is customary to remove a piece of vas at least 1 cm after clamping. The ends are ligated and then folded back on themselves and sutured into position, so that the cut ends face away from each other. This will reduce the risk of recanalization at a later date. It is important to stress that the acceptor is not immediately sterile after the operation, usually until approximately 30 ejaculations have taken place (44). During this intermediate period, another method of contraception must be used. If properly performed, vasectomies are almost 100 per cent effective.

Following vasectomy, sperm production and hormone output are not affected. The sperm produced are destroyed intraluminally by phagocytosis. This is a normal process in the male genital tract, but the rate of destruction is greatly increased after vasectomy. Vasectomy is a simpler, faster and less expensive operation than tubectomy in terms of instruments, hospitalization and doctor's training. Cost-wise, the ratio is about 5 vasectomies to one tubal ligation.

COMPLICATIONS

The very few complications that may arise are:
(a) Operative: The early complications include pain, scrotal haematoma and local infection. Wound infection is reported to occur in about 3 per cent of patients. Good haemostasis and administration of antibiotics will reduce the risk of these complications.
(b) Sperm granules: Caused by accumulation of sperm, these are a common and troublesome local complication of vasectomy. They appear in 10–14 days after the operation. The most frequent symptoms are pain and swelling. Clinically the mass is hard and the average size approximately 7 mm. Sperm granules may provide a medium through which re-anastomosis of the severed vas can occur. The sperm granules eventually subside. It has been reported that using metal clips to close the vas may reduce or eliminate this problem.
(c) Spontaneous recanalization: Most epithelial tubes will recanalize after damage, and the vas is no exception. The incidence of recanalization is variously placed between 0 to 6 per cent. Its occurrence is serious. Therefore, the surgeon must explain the possibility of this complication to every acceptor prior to the operation, and have written consent acknowledging this fact. In a study, the wives of 6 out of 14,047 men who had vasectomies in the UK became pregnant between 16 months and 3 years later (110). Therefore, the patient should be urged to report for a regular follow-up, may be up to 3 years.
(d) Autoimmune response: Vasectomy is said to cause an autoimmune response to sperm. Blocking of the vas causes reabsorption of spermatogonia and subsequent development of antibodies against sperm in the blood. Normally 2 per cent of fertile men have circulating antibodies against their own sperm. In men who have had vasectomies, the figure can be as high as 54 per cent. There is no reason to believe that such antibodies are harmful to physical health. It is likely that the circulating antibodies can cause a reduction in subsequent fertility despite successful reanastomosis of the vas (43).
(e) Psychological: Some men may complain of diminution of sexual vigour, impotence, headache, fatigue, etc. Such adverse psychological effects are seen in men who have undergone vasectomy under emotional pressure. That is why it is important to explain to each acceptor the basis of the operation and give him sufficient time to make up his mind voluntarily and seriously to have the operation done.

Causes of failure (109)

The failure rate of vasectomy is generally low, 0.15 per 100 person-years. The most common cause of failure is due to the mistaken identification of the vas. That is, instead of the vas, some other structure in the spermatic cord such as thrombosed vein or thickened lymphatic has been taken. Histological confirmation has, therefore, been recommended on all vasectomy specimens by some authors in developed countries. In developing countries, histological confirmation is ruled out because of lack of facilities for such an examination. A simpler method has been recommended, that is, microscopic examination of a smear prepared by gentle squeezing of the vas on a glass slide and staining with Wright's stain. The vas can be identified by the presence of columnar epithelial cells that line the lumen of the vas. In some cases, failure may be due to spontaneous recanalization of vas. Sometimes there may be more than one vas on one side. Pregnancy could also result from sexual intercourse before the disappearance of sperms from the reproductive tract.

Post-operative advice

To ensure normal healing of the wound and to ensure the success of the operation, the patient should be given the following advice:

1. The patient should be told that he is not sterile immediately after the operation; at least 30 ejaculations may be necessary before the seminal examination is negative (44).
2. To use contraceptives until aspermia has been established.
3. To avoid taking bath for at least 24 hours after the operation.
4. To wear a T-bandage or scrotal support (langot) for 15 days and to keep the site clean and dry.
5. To avoid cycling or lifting heavy weights for 15 days; there is, however, no need for complete bed rest.
6. To have the stitches removed on the 5th day after the operation.

No scalpel vasectomy

No scalpel vasectomy is a new technique that is safe, convenient and acceptable to males. This new method is

age, weight-for-height, and arm circumference. The last two are independent of age and are particularly useful when age is not known.

**CARE OF THE PRE-SCHOOL CHILD**

Children between 1–4 years of age are generally called pre-school age children or toddlers. In the history of health services of many developing countries, their social and health needs were realized rather late. Today, more than ever before, the pre-school age child has become a focus for organized medical-social welfare activities, and their death rate is considered a significant indicator of the social situation in a country.

The pre-school age is distinguished by the following characteristics:

1. **Large numbers**

   Pre-school age children (1–4 years) represent about 9.7 per cent of the general population in India. A large majority of these children live in rural and tribal areas and in urban slums. By virtue of their numbers, they are entitled to a large share of health and social services. Further, children are the human resources of the future. Their development is in the interest of the total national development; therefore, they need special attention. Unfortunately, pre-school age children are comparatively less attended to.

2. **Mortality**

   The pre-school age (1–4 years) mortality in India is 2.3 per cent of all deaths. This high mortality which is largely due to infection and malnutrition is characteristic of this age group in underprivileged areas. Malnutrition was shown to be an underlying cause in 3.4 per cent of all deaths in young children and associated cause in no less than 46 per cent.

3. **Morbidity**

   The data on the extent of morbidity of pre-school children are scarce. Some hospital records and a few surveys suggest that children in this age group are usually victims of PEM accompanied by retarded growth and development. Surveys indicate that the main morbidity problems are malnutrition and infections. The prevalence of severe protein-energy malnutrition ranged between 5–6 per cent, and mild protein energy malnutrition about 40 per cent. PEM is often associated with other nutritional deficiency such as anemia, xerophthalmia, etc. Diarrhoea, diphtheria, tetanus, whooping cough, measles and other eruptive fevers, skin and eye infections, and Intestinal parasitic infestations are usually common under the existing environmental conditions. At least 5 per cent of the pre-school age children belonging to poor socio-economic groups show signs of vitamin A deficiency. Accidents are also becoming frequent, especially burns and trauma from home accidents, and to an increasing degree, traffic accidents. Some childhood diseases and conditions do not kill their victims, but cause serious disability (e.g., blindness, paralysis); and some diseases become manifest later in life (e.g., heart disease and mental retardation). In many developing countries, periods of illness take up 25–30 per cent of the child’s life and each represents either loss of weight or failure to gain weight. These episodes are well documented by several authors.

4. **Growth and development**

   The importance of the first 5 or 6 years of life of a child for its growth and development is well known. Any adverse influences operating on children during this period (e.g., malnutrition and infection) may result in severe limitations in their development, some of which at least are irreversible. The concept of vulnerability calls for preventive care and special actions to meet the biological and psychological needs inherent in the process of human growth and development.

5. **Accessibility**

   While the infant may be easily reached, the toddler is hard to reach, and it is therefore difficult to look after his health. Special inputs are needed (e.g., day care centres, play group centres, children’s clubs) to reach the toddler and to bring him into the orbit of health care. Operation research all over the world has demonstrated that parents are unlikely to travel more than 5–8 kms to obtain medical care. For the toddler who needs to be carried, the distance may be reduced even further.

6. **Prevention in childhood of health problems in adult life**

   Results of research indicate how events in early life (e.g., child’s diet, infections) affect its health when it becomes an adult, and how many conditions can be prevented through early action, for example, dental diseases in adulthood. Early treatment of streptococcal infection can prevent rheumatic heart disease. Longitudinal studies suggest that the foundations of obesity, hypertension, cardiovascular diseases, and certain mental disorders may be laid in early life. Some of the chronic orthopaedic ailments of the adult are probably connected with anomalies in the development or minor uncorrected infirmities of the infant (e.g. talipes, congenital dislocation of the hip). Many of the measures subsequently undertaken to treat these disorders often do not fully succeed.

   Since young children are “vulnerable” to social and health hazards which can retard or arrest their physical and mental development during these critical years, they deserve special attention by the administration, general population and the family.

**CHILD HEALTH PROBLEMS**

The problems facing the health worker in the developing world are vast and are nowhere more evident than in the field of childcare. The main health problems encountered in the child population comprise the following:

1. **low birth weight;**
2. **malnutrition;**
3. **infections and parasitosis;**
4. **accidents and poisoning;** and
5. **behavioural problems.**

1. **Low birth weight**

   This has been discussed in detail earlier.

2. **Malnutrition**

   Malnutrition is the most widespread condition affecting the health of children. Scarcity of suitable foods, lack of purchasing power of the family as well as traditional beliefs and taboos about what the baby should eat, often lead to an insufficient balanced diet, resulting in malnutrition. It is estimated that no less than 45 per cent of the children who died before the age of 5 years were found to have malnutrition as underlying factor and 80 per cent of newborns.
mortality occurs in babies who are of low birth weight (57). During 2010-15, more than 14 per cent of the world's children under the age of 5 years were underweight for their age. The proportion ranged from 2 per cent of children in developed countries up to 30 per cent in developing countries (57). In India, the National Family Health Survey (NFHS) 2015-16 included survey of the nutritional status of young children. Both chronic and acute undernutrition were found to be high in all the 7 states for which reports have been received, namely, Haryana, Karnataka, Maharashtra, Orissa, Tamil Nadu, Uttar Pradesh and Goa.

At present in India 35.7 per cent children under 5 years age are underweight, of these, 7.5 per cent have moderate to severe wasting and 38.4 per cent moderate to severe stunting (58).

Malnutrition makes the child more susceptible to infection, recovery is slower and mortality is higher. Undernourished children do not grow to their full potential of physical and mental abilities. Malnutrition in infancy and childhood leads to stunted growth. It also manifests by clinical signs of micronutrient and vitamin deficiencies. Prevention and appropriate treatment of diarrhoea, measles and other infections in infancy and early childhood are important to reduce malnutrition rates as Infection and malnutrition often make vicious cycles. Exclusive breast-feeding in first 6 months of life is very important.

Specific nutritional deficiencies

(a) Protein-energy malnutrition

Protein-energy malnutrition (PEM) has been identified as a major health and nutrition problem in India. It occurs particularly in weaklings and children in the first years of life. It is characterized by low birth weight if the mother is malnourished, poor growth in children and high level of mortality in children between 12 and 24 months, and is estimated to be an underlying cause in 30 per cent of deaths among children under age 5.

As many as 34 per cent of the children in the developing world have low height for their age i.e. stunting, and 16 per cent children have low weight for height. The rate of low height for age reflects the cumulative effects of undernutrition and infections since birth or even before birth; high rates are often suggestive of bad environmental conditions and/or early malnutrition. On the other hand, a greater frequency of low weight for height, often reflects current severe undernutrition or disease.

(b) Micronutrient malnutrition

Micronutrient malnutrition refers to a group of conditions caused by deficiency of essential vitamins and minerals such as vitamin A, calcium, iodine, iron and zinc. It is estimated that about 2 billion people are affected by this type of malnutrition. Vitamin A deficiency is still the most common cause of preventable childhood blindness world-wide; iodine deficiency causes goitre, cretinism and brain damage; and anaemia results from insufficient iron intake.

Nutritional anaemia: It affects all age groups, including pre-school children, school children and elders. Even mild anaemia reduces resistance to fatigue. It has a profound effect on psychological and physical behaviour.

Vitamin A deficiency and nutritional blindness: Young children are at greater risk of developing xerophthalmia, partly because their vitamin A requirements are proportionately greater than those of any other group and partly because they suffer most from infections. The result is that severe, blinding corneal destruction is most frequently seen in children between the age of six months and six years. Vitamin A deficiency is in fact, the single most frequent cause of blindness among pre-school children in developing countries. Some 20 per cent children with this deficiency are at increased risk of death from common infections, and around 2 per cent are blinded or suffer serious sight impairment.

Iodine deficiency: Iodine deficiency disorders pose a public health problem as about 1.5 billion people are living in environments lacking this mineral. As a result at least 30,000 babies are stillborn each year and over 120,000 are born mentally retarded, physically stunted, deaf-mute or paralysed. Even when children are born otherwise healthy, lack of iodine may still cause mental dullness and apathy.

Nutritional deficiencies not only lead to severe illnesses, entailing long and costly treatment, but also influence physical development, psychic behaviour and susceptibility to infection.

3. Infectious and parasitic diseases

Young children fall an easy prey to infectious diseases. The leading childhood diseases are: diarrhoea, respiratory infections, measles, pertussis, polio, neonatal tetanus, tuberculosis, and diphtheria. It is known that a child may get affected several times in a year; the incidence increases with the aggravation of a state of malnutrition. Of about 4 million deaths a year from acute respiratory infections in the developing world, a quarter are linked to malnutrition, and a further quarter associated with complications of measles, pertussis, malaria and HIV/AIDS. During 2015, about 9 per cent of under-five mortality worldwide was due to diarrhoeal diseases. About 13 per cent due to ARI, about 1 per cent deaths were due to measles and about 5 per cent due to malaria. In India, during the year 2017, 5,293 cases of diphtheria, 17,068 cases of measles, 23,779 cases of pertussis, and 295 cases of neonatal tetanus were reported (59). The actual figures may be several times higher since there is considerable under-reporting. This is so, for example, in the case of eruptive fevers, malaria, intestinal parasites such as ascariasis, hookworm, giardiasis and amoebiasis etc. which are common because of poor environmental sanitation and paucity of potable drinking water. The prevention and treatment of children's illnesses may interrupt the transmission of infection in the community.

These few facts, which are merely examples and could be multiplied, show that the prevention and treatment of infections and parasitosis of children are bound to have important long-term consequences.

4. Accidents and poisoning

In the developed world, accidents and poisoning have become a relatively more important child health problem. There is every reason to believe that accidents among children are frequent in the developing countries also, especially burns and trauma as a result of home accidents and, to an increasing degree, traffic accidents. Children and young adolescents are particularly vulnerable to domestic accidents — including falls, burns, poisoning and drowning.

5. Behavioural problems

Behavioural disturbances are notable child health problem, the importance of which is increasingly recognized in most countries. Children abandoned by their families present severe social and health problems. Over 60,000 children are abandoned each year in India (60).
6. Other factors affecting the health of children

a. Maternal health

A major determinant of child health is the health of his/her mother. Child health is adversely affected (the risk begins to appear even before birth) if the mother is malnourished, if she is under 18 years (too young) or over 35 (too old), if her last child was born less than 2 years ago (too close), if she has already more than 4 births (too many) and if she is deprived of basic pregnancy care. A healthy mother brings forth a healthy baby, with better chances of survival.

b. Family

In pre-school years, the child is very much an organic part of the immediate family. Whatever happens to him or her affects the other members of the family, and vice versa. Therefore, “child health” has to be “family health”. It depends upon the family's physical and social environment, which includes its lifestyle, customs, culture, traditional habits, and the childbearing and childrearing practices. Other factors affecting the health of children include family size, family relationships, and family stability. Infancy and early childhood is the time when the child contracts common contagious illness from contact with others (older brothers and sisters, playmates, schoolmates). Data shows that the number of episodes of infectious diarrhoea increases with the size of the family. Studies also show an increase in the prevalence of malnutrition in families with more than 4 children. In short, fewer children would mean better nutrition, better health care, less morbidity and lower infant mortality.

c. Socio-economic circumstances

The socio-economic situation in which the family is placed is a very important factor in child health. In every region of the world, the physical and intellectual development of children varies with the family's socio-economic level. Under-privileged children of the same age are smaller, lighter and less advanced in psychomotor and intellectual performance, compared to children of privileged groups. A detailed analysis of socio-economic factors shows the part played by the parents' education, profession and income, their housing, the urban or rural, industrialized or non-industrialized nature of the population.

Poverty, illiteracy (especially mothers' illiteracy) and sickness create a vicious circle spanning from one generation to the next, and from which it is difficult for the individual to escape. The differences in health between rich and poor, which can be observed in all age-groups are particularly striking among children.

d. Environment

After the first week of a child's life, the environmental factors play a very great role as determinants of infant and childhood morbidity and mortality. Tetanus infection of the newborn may take a heavy toll of the newborn in the first few weeks of life. Diarrhoea, pneumonia and other infections – bacterial, viral and parasitic – are extremely common in children exposed to insanitary and hostile environment. The stages at which these infections occur vary according to the ecological conditions, home and family hygiene, local epidemiological conditions and the extent to which they come into contact with earth, water and above all with adults and other children. An insufficient supply of safe water, inadequate disposal of human excreta and other waste, an abundance of insects and other disease carriers are among the environmental factors continuously menacing family health.

Another important factor which influences child development is environmental stimulations. Children also develop skills if they are given the opportunity. Stimulation, particularly the interaction with people who take interest and talk to them helps children to develop. Other sources of environmental stimulation are the radio, TV and illustrated magazines.

e. Social support and health care

Other factors affecting the health status of children include community and social support measures, ranging from creches and day care facilities to organized health care systems.

**RIGHTS OF THE WOMEN AND CHILDREN**

Women and children are the most vulnerable section of the society. It is, therefore, vital to improve their health and well-being in order to achieve complete development of overall human resources.

One of the core functions assigned to the WHO in its Constitution of 1948 was to “promote maternal and child health and welfare”. By the 1950s, national health plans and policy documents from development agencies invariably stressed that mothers and children were vulnerable groups and, therefore, priority “targets” for public health action. The notion of mother and children as vulnerable group was also central to the primary health care movement launched at Alma-Ata in 1978. The plight of mothers and children soon came to be seen as much more than a problem of biological vulnerability. The 1987 Call to Action for Safe Motherhood explicitly framed it as “deeply rooted in the adverse social, cultural and economic environment of the society, and specially the environment that societies create for women”. Women’s relative lack of decision-making power and their unequal access to employment, finances, education, basic health care and other resources are considered to be the root causes of their ill-health, and that of their children. The unfairness of this situation has made it obvious that the health of mothers and children is an issue of rights, entitlements and day to day struggle to secure these entitlements. The milestones in this establishment of the rights of women and children are as shown in Fig. 9 (61).

**RIGHTS OF THE CHILD**

One of the most encouraging signs of our times is the awakening of the public to the needs and rights of children. The needs of children and our duties towards them are enshrined in our Constitution; the relevant articles are:

a. Article 24 prohibits employment of children below the age of 14 in factories;

b. Article 39 prevents abuse of children of tender age; and

c. Article 45 provides for free and compulsory education for all children until they complete the age of 14 years.

In the country’s Five Year Plans, special attention has been given to the welfare of children particularly the weaker sections. Various schemes have been introduced and implemented to achieve this goal. However, despite constitutional provisions, organized efforts for stepping up child welfare services did not take place until 1959.
The Universal Declaration of Human Rights states that "motherhood and childhood are entitled to special care and assistance".

The Declaration of the Rights of the Child

The Convention on the Elimination of All Forms of Discrimination Against Women enjoins States parties to ensure appropriate maternal health services.

At the United Nations World Summit on Children governments declare their "joint commitment... to give every child a better future" and recognize the link between women's rights and children's well-being.

The United Nations Human Rights Committee expresses concern over high rates of maternal mortality.

The United Nations Human Rights Committee rules that when abortion gives rise to a criminal penalty even if a woman is pregnant as a result of rape, a woman's right to be free from inhuman and degrading treatment might be violated.

The United Nations Committee on the Rights of the Child states that adolescent girls should have access to information on the impact of early marriage and early pregnancy and have access to health services sensitive to their needs and rights.

The United Nations Committee on the Rights of the Child adopts its General Comment on HIV/AIDS and that on the Rights of the Child.

The United Nations Committee Against Torture calls for an end to the extraction of confession for prosecution purposes from women seeking emergency medical care as a result of illegal abortion. The United Nations Special Rapporteur on the Right to Health reports that all forms of sexual violence are inconsistent with the right to health.

Milestones in the establishment of the rights of women and children

1. Right to develop in an atmosphere of affection and security and, wherever possible, in the care and under the responsibility of his/her parents;
2. Right to enjoy the benefits of social security, including nutrition, housing and medical care;
3. Right to free education;
4. Right to full opportunity for play and recreation;
5. Right to a name and nationality;
6. Right to special care, if handicapped;
7. Right to be among the first to receive protection and relief in times of disaster;
8. Right to learn to be a useful member of society and to develop in a healthy and normal manner and in conditions of freedom and dignity;
9. Right to be brought up in a spirit of understanding, tolerance, friendship among people, peace and universal brotherhood; and
10. Right to enjoy these rights, regardless of race, colour, sex, religion, national or social origin.

UN DECLARATION OF THE RIGHTS OF THE CHILD

The year 1959 ushered in a new era in child welfare. To meet the special needs of the child, the General Assembly of the United Nations adopted on 20th November 1959, the Declaration of the Rights of the Child. India was a signatory to this Declaration. The Rights of the Child are:

- **Right to development:** In an atmosphere of affection and security and, wherever possible, in the care and under the responsibility of his/her parents.
- **Right to social benefits:** Including nutrition, housing, and medical care.
- **Right to education:** Free education.
- **Right to recreation:** Full opportunity for play and recreation.
- **Right to name and nationality:**
- **Right to special care:** If handicapped.
- **Right to protection:** To be among the first to receive protection and relief in times of disaster.
- **Right to be a useful member:** Of society and to develop in a healthy and normal manner and in conditions of freedom and dignity.
- **Right to understand:** The spirit of understanding, tolerance, friendship among people, peace, and universal brotherhood.
- **Right to enjoy rights:** Regardless of race, colour, sex, religion, national or social origin.

UNIVERSAL CHILDREN'S DAY

November 14 is observed as Universal Children's Day. It was started by the International Union for Child Welfare and the UNICEF. In 1954, the UN General Assembly passed a formal resolution establishing Universal Children's Day and assigned to UNICEF the responsibility for promoting this annual day.

A non-governmental organization (Defence for Children International, Geneva) was set up in 1979 during the International Year of the Child. It was directed towards promoting and protecting the Rights of the Child.

The 1990 World Summit for Children agreed on a series of specific social goals for improving the lives of the children including measurable progress against malnutrition.
preventable diseases and illiteracy. The vital vulnerable years of childhood should be given a first call on society’s concerns and capacities. A child has only one chance to develop normally, and the protection of that one chance, therefore, demands the kind of commitment that will not be superseded by other priorities. The following are the goals that have been accepted by almost all nations.

Social goals for the year 2000 (62)

The end-of-century goals agreed to by the nations following the 1990 World Summit for children were:

1. A one-third reduction in 1990 under-five death rates (or to 70 per 1000 live births, whichever is less);
2. A halving of 1990 maternal mortality rates;
3. A halving of 1990 rates of malnutrition among the world’s under-five (to include the elimination of micronutrient deficiencies, support for breast-feeding by all maternity units, and a reduction in the incidence of low birth weight to less than 10 per cent);
4. Achievement of 90 per cent immunization among under-ones, eradication of polio, elimination of neonatal tetanus, a 90 per cent reduction in measles cases and a 95 per cent reduction in measles deaths (compared to pre-immunization level);
5. A halving of child deaths caused by diarrhoeal disease;
6. A one-third reduction of child deaths from acute respiratory infections;
7. Basic education for all children and completion of primary education by at least 80 per cent girls as well as boys;
8. Clean water and safe sanitation for all communities;
9. Acceptance in all countries of the Convention on the Rights of Child, including improved protection for children in especially difficult circumstances; and
10. Universal access to high quality family planning information and services in order to prevent pregnancies that are too early, too closely spaced, too late or too many.

NATIONAL POLICY FOR CHILDREN

Keeping in view the constitutional provisions and the United Nations Declaration of the Rights of the Child, the Government of India adopted a National Policy for Children in August 1974. The Policy declares:

“It shall be the policy of the State to provide adequate services to children, both before and after birth and through the period of growth, to ensure their full physical, mental and social development. The State shall progressively increase the scope of such services so that, within a reasonable time, all children in the country enjoy optimum conditions for their balanced growth”.

According to the Declaration, the development of children has been considered an integral part of national development. The Policy recognizes children as the “nation’s supremely important asset” and declares that the nation is responsible for their “nurture and solicitude”. It further spells out various measures to be adopted and priorities to be assigned to children’s programmes with a focus on areas like child health, child nutrition and welfare of the handicapped and destitute children.

A high level National Children’s Board with the Prime Minister as Chairman was established. It provides a forum where problems relating to child welfare and their purposeful development into useful members of society are evolved, reviewed and coordinated into an effective programme (63).

Following the enunciation of the National Policy for Children, a number of programmes were introduced by the Government of India, viz. The ICDS Scheme, programmes of supplementary feeding, nutrition education and production of nutritious food, constitution of the “National Children’s Fund” under the Charitable Endowments Act, 1980, institution of National Awards for Child Welfare, Welfare of the Handicapped (64).

Review of existing policies and legislations (65)

The Constitution of India follows the principle of protective discrimination and thereby commits itself to safeguard the rights of children through policies, laws and action. These commitments are reflected through the national policies which are as follows:

1. National Policy for Children, 1974 provides the conceptual basis for an integrated approach to address the whole child and commits the State to provide adequate services to children, both before and after birth and through the period of growth, to ensure their full physical, mental and social development.
2. National Policy on Education, 1986 and its National Plan of Action, which has a full section on early childhood care and education. It clearly recognizes the holistic nature of child development, and that ECCE is the crucial foundation for human resource development and cumulative lifelong learning. It is viewed as a feeder and support programme for universal elementary education – especially for first generation learners, and an important support service for working mothers and girls.
3. The National Children’s Fund was created during the international year of the child in 1979 under the Charitable Endowment Fund Act, 1890. The fund provides financial assistance to voluntary agencies for implementing programmes for the welfare of children including rehabilitation of destitute children.
4. National Health Policy, 2002 accords primacy to preventive and first line curative care at primary health level, and emphasizes convergence, and strategies to change care behaviours in families and communities.
5. National Charter for Children, 2003 intends to secure for every child its inherent right to be a child and enjoy a healthy and happy childhood, to address the root causes that negate the healthy growth and development of children, and to awaken the conscience of the community in the wider societal context to protect children from all forms of abuse, while strengthening the family, society and the nation. The national charter for children affirms India’s commitment to the child. However, it does not declare India’s acceptance of children’s entitlements as their rights. The national policy for children, 1974 still stands as the official policy commitment to children of India. With India’s accession to the UNCRC and its two optional protocols rights based framework has been accepted as the guiding frame for policy measures and programming for children. This is clearly reflected in the national plan of action for children, 2005.
6. Commission for the Protection of Child Rights Act, 2005 provides for the constitution of a national commission and state commissions for protection of
child rights and children’s courts for providing speedy trial of offences against children or of violation of child rights and for matters connected therewith or incidental thereto.

7. National Plan of Action for Children, 2005 articulates clearly the rights, perspective, and agenda for the development of children. It provides a robust framework within which to promote the development and protection of children. The guiding principles of the NPA are:

a. To regard the child as an asset and a person with human rights;

b. To address issues of discrimination emanating from biases of gender, class, caste, race, religion and legal status in order to ensure equality;

c. To accord utmost priority to the most disadvantaged, poorest of the poor and the least served child in all policy and programme interventions; and

d. To recognize the diverse stages and settings of childhood, and address the needs of each, providing all children the entitlements that fulfill their rights and meet their needs in each situation.

Time targets in the NPAC 2005 extend to 2012, the end-year of the Eleventh Plan. The NPAC 2005 has identified 12 key priority areas for the highest and most sustained attention in terms of outreach, programme interventions and resource allocations. These are:

- Reducing infant mortality rate.
- Reducing maternal mortality rate.
- Reducing malnutrition among children.
- Achieving 100% civil registration of births.
- Universalization of early childhood care and development and quality education for all children achieving 100% access and retention in schools, including pre-schools.
- Complete abolition of female foeticide, female infanticide and child marriage and ensuring the survival, development and protection of the girl child.
- Improving water and sanitation coverage in both rural and urban areas.
- Addressing and upholding the rights of children in difficult circumstances.
- Securing for all children all legal and social protection, from all kinds of abuse, exploitation and neglect.
- Complete abolition of child labour with the aim of progressively eliminating all forms of economic exploitation of children.
- Monitoring, review, and reform of policies, programmes and laws to ensure protection of children’s interest and rights.
- Ensuring child participation and choice in matters and decisions affecting their lives.

A new alienation of children from their rights has arisen with the plight of children affected by HIV-AIDS. Since the finalization of the NPAC the issues of these children have also been accepted as key priorities by MWCD and therefore found a place in the Eleventh Plan among critical concerns that need to be addressed.

8. Integrated Child Protection Scheme (ICPS) (66, 67)

During the year 2009-10, the Ministry of Women and Child Development launched a new centrally sponsored scheme called “Integrated Child Protection Scheme” (ICPS) with a view to create a safe and secure environment in the country for the comprehensive development of children who are in need of care and protection, children in conflict and in contact with law (either as a victim or as a witness or due to any other circumstances), children of migrant families, children of prisoners, prostitutes, working children, street children, trafficked or sexually exploited children, child drug abusers, child beggars etc.

The objectives of the scheme are: (1) Improve access to and quality of child protection services; (2) Raise public awareness about child rights; (3) Clearly articulated responsibilities and accountability for child protection; (4) Establish structures at all government levels for delivery of statutory and support services to children in difficult circumstances; and (5) Setting-up of an evidence based monitoring and evaluation system.

The services provided under ICPS are as follows:

(1) Emergency outreach service through ‘Child line’, dedicated number is 1098. It is a 24-hour toll-free telephone service available to all children in distress.
(2) Open shelters for children in need, in urban and semi-urban areas.
(3) Family based non-institutional care through sponsorship, foster-care, adoption, cradle baby centres and after-care.
(4) Institutional services through shelter homes, children homes, observation homes, special homes, and specialized services for children with special needs.
(5) Web-enabled child protection management system including website for missing children.
(6) General grant-in-aid for need based Interventions.

9. National Policy for Children 2013 (NPC) (68)

The National Policy for Children 2013 is a long term sustainable, multi-sectoral, and integrated approach for the development and protection of children i.e. 0-18 years age group. Survival, health, nutrition, development, education, protection and participation are the key priorities of the policy. It reiterates the State’s commitment to ensure equitable access to essential, preventive, promotive, curative and rehabilitative health care for all children. Towards this goal, NPC envisages that state shall take measures to:

- Improve maternal health care (pre-natal, natal, post-natal);
- Provide universal access to services for informed choices related to births and spacing;
- Address key causes of child mortality through appropriate interventions including access to safe drinking water and sanitation;
- To improve new born and child care practices;
- To protect children from water borne, blood borne, vector borne, communicable and other childhood diseases by providing universal and affordable access to appropriate services;
- Prevent disabilities, physical and mental through timely measures to take pre-natal, natal, peri-natal and post-natal care of mother and child.
- Ensure availability of services, support and provisions for nutritive attainment in a life cycle approach with focus on infant and young child feeding (IYCF) practices and on the health and nutrition needs of adolescent girls and other vulnerable groups.
The growing vulnerability of children in urban settlements, including those caught in the shifting frame of migratory and transient labour are also now in the MWCD protection.

The state commits to allocate the required financial, material and human resources for the implementation of NPC 2013. The Ministry of Women & Child Development is the nodal ministry for implementation of NPC.

In order to effectively address the heinous crime of sexual abuse and sexual exploitation of children through less ambiguous and more stringent legal provisions, the Ministry of Women and Child Development introduced the Protection of Children from Sexual Offence (POCSO) Act, 2012.

The Act defines a child as any person below 18 years of age and regards the best interest and well-being of a child as being of paramount importance at every stage, to ensure a healthy physical, emotional, intellectual and social development of the child. It defines different forms of sexual abuse, including penetrative and non-penetrative assault, as well as sexual harassment and pornography, and deems a sexual assault to be "aggravated" under certain circumstances, such as when abused child is mentally ill or when the abuse is committed by a person in a position of trust or authority vis-a-vis the child, like a family member, police officer, teacher or doctor. People who traffic children for sexual purpose are also punishable under the provisions relating to abetment in the said Act (69).

An ordinance providing the death penalty for rapist of girls below 12 years of age “The Criminal Law Amendment Ordinance, 2018” was promulgated. The salient features of the Ordinance are:

a. Minimum punishment for rape made 10 years;
b. Minimum punishment of 20 years to a person committing rape on a girl aged below 16 years;
c. Minimum punishment of 20 years rigorous imprisonment and maximum death penalty / life imprisonment for committing rape on a girl aged below 12 years;
d. Police officer committing rape anywhere shall be awarded rigorous imprisonment of minimum 10 years;
e. Investigation of rape cases to be completed within 2 months;
f. Appeals in rape cases to be disposed within 6 months; and

g. No anticipatory bail can be granted to a person accused of rape of girl of age less than 16 years.

The Government of India adopted a new National Plan of Action for Children (NPAC) 2016 which is based on the principles embedded in earlier Action Plan. The Action Plan has four key priority areas: survival, health and nutrition; education and development; protection and participation. The NPAC seeks to ensure convergence of ongoing programmes and initiation of new programmes so as to focus on objectives through well-defined strategies and activities to achieve desired level of outcome for children.

Goals and targets set by Government of India for child health under various national and international commitments are as follows (65):

### CHILD HEALTH GOALS/TARGETS

#### Common Minimum Programme

To raise public spending on health to at least 2-3% of GDP over the next five years and focus on primary health care...special attention will be paid to the poorer sections in the matter of health care.

#### Twelfth Five Year Plan 2012-17

- Reduction of infant mortality rates to 25 per thousand live births by 2017.
- To raise the sex ratio for age group 0–6 from 914 to 950 by 2017.
- Prevention and reduction of under-nutrition in children under 3 years to half of NFHS-3 (2005–06) levels
- To reduce infant mortality rate to below 30 per 1000 live births by 2010
- To reduce child mortality rate to below 31 per 1000 live births by 2010.
- To reduce neonatal mortality rate to below 16 per 1000 live births by 2020.
- To explore possibilities of covering all children with plan for health insurance
- To reduce by two-thirds, between 1990 and 2015, the under-five mortality rate (Goal 4).
- To reduce by three-quarters, between 1990 and 2015, the maternal mortality rate.
- To combat HIV/AIDS, malaria and other diseases
- To reduce under five mortality to 23 per 1000 live births by 2025.
- To reduce infant mortality rate to 28 by 2019.
- To reduce neo-natal mortality to 16 and stillbirth rate to “single digit” by 2025.
- To increase life expectancy at birth from 67.5 to 70 years by 2025.
- To reduce prevalence of blindness to 0.25/1000 by 2025, and reduce disease burden by one third from current level.

#### Millennium Development Goals (MDG)

- To reduce by three-quarters, between 1990 and 2015, the under-five mortality rate (Goal 4).
- To reduce by three-quarters, between 1990 and 2015, the maternal mortality rate.
- To combat HIV/AIDS, malaria and other diseases
- To reduce under-five mortality to 23 per 1000 live births by 2025.
- To reduce infant mortality rate to 28 by 2019.
- To reduce neo-natal mortality to 16 and stillbirth rate to “single digit” by 2025.
- To increase life expectancy at birth from 67.5 to 70 years by 2025.
- To reduce prevalence of blindness to 0.25/1000 by 2025, and reduce disease burden by one third from current level.

#### National Health Policy, 2017

- To reduce under five mortality to 23 per 1000 live births by 2025.
- To reduce infant mortality rate to 28 by 2019.
- To reduce neo-natal mortality to 16 and stillbirth rate to “single digit” by 2025.
- To increase life expectancy at birth from 67.5 to 70 years by 2025.
- To reduce prevalence of blindness to 0.25/1000 by 2025, and reduce disease burden by one third from current level.
DELIVERING THE MCH SERVICES

MCH (mother and child health) is not a new specialty. It is a method of delivering health care to special group in the population which is especially vulnerable to disease, disability or death. These groups (i.e., children under the age 5 years and women in the reproductive age group (15-44 years)) comprise about 32.4 per cent of the total population in India.

The MCH services encompass the curative, preventive and social aspects of obstetrics, paediatrics, family welfare, nutrition, child development and health education. The specific objectives of MCH are:

1. reduction of morbidity and mortality rates for mothers and children;
2. promotion of reproductive health; and
3. promotion of the physical and psychological development of the child within the family.

Through concern with child development and the health education of parents and children, the ultimate objective of MCH services is life-long health.

Sub-areas

The components of MCH include the following sub-areas:

- maternal health
- family planning
- child health
- school health
- handicapped children
- care of the children in special settings such as day care centres.

The content of MCH care will vary according to the demographic, social and economic patterns. Factors such as urbanization, rural migration, changing patterns of women's work and status have far-reaching effects on childbearing and child-rearing. It is now generally accepted that the MCH services should always be flexible and based on, and adapted to the local needs and resources of the community it serves; they should be moulded to the local traditions, cultures and other environmental characteristics and cannot be modelled on patterns copied from other countries. Health care, social legislation and social support measures also will have to be adapted to these changing needs and problems of the community.

MCH care is now conceived of as all activities which promote health and prevent or solve health problems of mother and children, irrespective of whether they are curative, diagnostic, preventive or rehabilitative, and whether they are carried out in health centres or in the home by primary health care workers, traditional dais, or highly trained specialists.

Recent trends in MCH care

Maternal and child care was traditionally designed and provided in the form of vertical programmes with "standard" technical content based on models from a few developed countries. Applied in different socio-economic situations, such vertical programmes have been unable to provide more than minimum coverage because of their cost, and they have scarcely been of a kind to solve the priority problems of the majority of mothers and children. The emergence of some new concepts is now changing the organization and management of MCH care in increasing number of countries (70). These are discussed below:

1. Integration of care

Conventional MCH services tended to be fragmented into antenatal care, postnatal care, infant care, family planning etc. The various components were dealt with separately by different staff or departments. This approach has changed over the years. The trend now is an "integrated" approach. This integration is based on the fact that it is inconvenient for the mother to go to one place to receive care for herself, to another for care for her children, and yet another for family planning services.

An integrated approach implies that all those involved in maternity care from the obstetrician down to the local dais, must work as a team. Obstetric and paediatric units should work as a team. Obstetric and paediatric units should

2. Risk approach

A promising means of improving the coverage and efficiency of MCH care and family planning is the "risk approach". This is a managerial tool for better use of scarce resources. It is based on the early detection of mothers and children with high-risk factors. All mothers and children with
high risk factors are given additional and more skilled care including hospitalization, while at the same time essential care is provided for the rest of the mothers and children so that every one gets care appropriate to their need.

It is also possible to assess the “degrees” of risk of each factor, by scoring according to their (a) magnitude – i.e., extent and severity; (b) treatability – responsiveness to treatment and control; (c) cost-effect – in terms of alleviating human suffering; and (d) community attitude – social concern. Such an approach when applied on a community-wide basis enables the determination of priority activities, within the MCH programme based on the “degrees” of risk.

Application of the risk approach to the problems of mothers and children is a departure from past or traditional practices to promote the health of mothers and children.

3. Manpower changes

The special category of “maternal and child health worker” (e.g., auxiliary-nurse-midwives, health visitors) at the peripheral level is gradually being phased out. A wide range of workers are now considered necessary for maternal and child health work. They include:

(i) **Professionals**: Specialists
(ii) **Field workers**: Multi-purpose workers, Health Guides, dais (traditional birth attendants), balsevikas, Anganwadi workers, extension workers, ASHA etc
(iii) **Voluntary workers**: Members of women’s organizations

Taking for example, the local dais in the past were not generally recognized by the national health authorities, who thought that their services were inimical to the safety of the mother and child. The current trend is to assist them perform safe deliveries through training and supervision. In India, where 70 per cent of population lives in rural areas, there are not enough obstetricians to attend to all deliveries. Therefore, a trained dai or midwife is absolutely essential in every village. The same thing can be said about paediatrics. It is now recognized that obstetric and paediatric services can only be improved by cooperation and liaison with these practitioners.

4. Primary health care

Primary health care is now recognized as a way of making essential health care available to all. It has all the elements necessary to make a positive impact on the health of mothers and children – i.e., MCH care, family planning, control of infections, education about health problems and how to prevent them, and measures to ensure nutritious food – all closely related. Primary health care emphasizes family oriented care and support, and community self-reliance in health matters. MCH care is an indispensable priority element of primary health care in every country.

**Targets for MCH Services**

From time to time Government of India has suggested MCH goals with quantifiable time bound targets for achievement. Table 11 shows the MCH indicators with their goal period and the current level of achievement.

**Organization of MCH/FP services**

The mother and child health, and family planning services were integrated in the Fourth Five Year Plan for better effectiveness. They both are now an integral part of primary health care, which places emphasis on community participation and intersectoral coordination. The National

Health Policy 2002 and National Population Policy 2000 has provided the necessary directives for reorienting and restructuring the health services, based on primary health care approach with short and long-term goals.

The infrastructure in rural areas is based on the complex of community health centres, primary health centres and their subcentres. They provide preventive and promotive health care services. Since deliveries by trained health personnel are crucial in reducing maternal and infant mortality in rural areas, the government of India undertook a scheme to train local dais to conduct safe deliveries. These dais are now available in most villages. Mention must be made of ICDS (Integrated Child Development Services) projects which are functioning all over the country providing a package of basic health services (eg. supplementary nutrition, Immunization, health check-up, referral, nutrition and health education, and non-formal education services) to mother and children.

Maternal health care was a part of family welfare programme from its inception. Interventions were introduced on vertical schemes, but family planning remained a separate intervention. In 1992, the Child Survival and Safe Motherhood Programme integrated all the schemes for better compliance. More recently, Reproductive and Child Health Programme was launched in 1997, which integrated family planning, Child Survival and Safe Motherhood Programme. Preventive management of STD/RTI, AIDS, and a client approach to health care. This programme has entered into phase II, with reorientation to make it consistent with the requirement of the National Rural Health Mission.

In urban areas, the general trend is towards institutional delivery. In larger cities, almost 90 per cent of deliveries take place in maternity hospitals and maternity homes. Some of the institutions are under the auspices of the Municipal Corporations and voluntary organizations. The services of obstetricians are available at district hospitals, which are the apical hospitals for MCH care at the district level. For specialized care of children, paediatric units have been established in several district hospitals.

Table 12 shows the evolution of maternal and child health programmes in India.

**INDICATORS OF MCH CARE**

Maternal and child health status is assessed through measurements of mortality, morbidity and, growth and development. In many countries, mortality rates are still the only source of information. Morbidity data are scarce and poorly standardized. In recent years, attention has been paid to systematizing the collection, interpretation and dissemination of data on growth and development. The commonly used mortality indicators of MCH care are:

1. Maternal mortality ratio
2. Mortality in infancy and childhood
   a. Perinatal mortality rate
   b. Neonatal mortality rate
   c. Post-neonatal mortality rate
   d. Infant mortality rate
   e. 1-4 year mortality rate
   f. Under-5 mortality rate
   g. Child survival rate

**MATERNAL MORTALITY RATIO**

According to WHO, a maternal death is defined as “the death of a woman while pregnant or within 42 days of termination of pregnancy, irrespective of the duration and site of pregnancy, from any cause related to or aggravated by the pregnancy or its management but not from accidental or incidental causes” (63).

Maternal mortality ratio measures women dying from “puerperal causes” and is defined as:

\[
\text{Total no. of female deaths due to complications of pregnancy, childbirth or within 42 days of delivery from "puerperal causes" in an area during a given year} \times \frac{1,000}{	ext{Total no. of live births in the same area and year}}
\]

Late maternal death : Complications of pregnancy or childbirth can also lead to death beyond the six-weeks postpartum period. In addition, increasingly available modern life-sustaining procedures and technologies enable more women to survive adverse outcomes of pregnancy and delivery, and to delay death beyond 42 days postpartum. Despite being caused by pregnancy-related events, these deaths do not count as maternal deaths in routine civil registration system. An alternative concept of late maternal death was included in ICD-10, in order to capture these delayed deaths that occur between six weeks and one year postpartum. It is defined as “the death of a woman from direct or indirect causes, more than 42 days but less than one year after termination of pregnancy” (72).

Pregnancy-related death : A pregnancy-related death is the death of a woman while pregnant or within 42 days of termination of pregnancy, irrespective of the cause of death (31).

**Statistical measures of maternal mortality** (71, 72)

(a) Maternal mortality ratio : Number of maternal deaths during a given time period per 100,000 live births during the same time-period.

(b) Maternal mortality rate : Number of maternal deaths in a given period per 100,000 women of reproductive age during the same time-period.

(c) Adult lifetime risk of maternal death : The probability...
of dying from a maternal cause during a woman's reproductive lifespan.

(d) The proportion of maternal deaths of women of reproductive age (PM): The number of maternal deaths in a given time period divided by the total deaths, among women aged 15–49 years.

The International Classification of Diseases (ICD) has recommended that maternal deaths may be disaggregated into two groups:

(1) Direct obstetric deaths: those resulting from obstetric complications of the pregnant state (pregnancy, labour and puerperium), from interventions, omissions, incorrect treatment, or from a chain of events resulting from any of the above.

(2) Indirect obstetric deaths: those resulting from previous existing disease or disease that developed during pregnancy and which was not due to direct obstetric causes, but which was aggravated by physiological effects of pregnancy.

The maternal mortality rate, the direct obstetric rate and the indirect obstetric rate are fine measures of the quality of maternity services.

The 43rd World Assembly in 1990 adopted the recommendation that countries consider the inclusion on death certificates of questions regarding current pregnancy and pregnancy within one year preceding death in order to improve the quality of maternal mortality data and provide alternative methods of collecting data on deaths during pregnancy or related to it, as well as to encourage the recording of deaths from obstetric causes occurring more than 42 days following termination of pregnancy.

Approaches for measuring maternal mortality

In the absence of complete and accurate civil registration systems, MMR estimates are based upon a variety of methods:

(1) Civil registration systems: This approach involves routine registration of births and deaths. Ideally, maternal mortality statistics should be obtained through civil registration data.

(2) Household survey: Where civil registration data are not available, household survey provides an alternative.

(3) Sisterhood methods: Sisterhood methods obtain information by interviewing a representative sample of respondents about the survival of all their adult sisters (to determine the number of ever married sisters, how many are alive, how many are dead, and how many died during pregnancy, delivery, or within six weeks of pregnancy).

(4) Reproductive-age mortality studies (RAMOS): This approach involves identifying and investigating the causes of all deaths of women of reproductive age in a defined area/population by using multiple sources of data.

(5) Verbal autopsy: This approach is used to assign cause of death through interview with family or community members, where medical certification of cause of death is not available. Records of births and deaths are collected periodically among small populations, under demographic surveillance systems maintained by the research institutions in developing countries.

(6) Census: A national census, with the addition of a limited number of questions, could produce estimates of maternal mortality; this approach eliminates sampling errors and hence allows a more detailed breakdown of the results, including time trends, geographic subdivisions and social strata.

Incidence

WORLD SCENARIO

The methodology employed by the Maternal Mortality Estimation Inter-Agency Group to estimate 1990–2015 maternal mortality ratio followed an improved approach referred to as Bayesian maternal mortality estimation model or B Mat model. These results supersede all previously published estimates for the years within that time period and differences with previously published estimates should not be interpreted as representing time trends (1).

An estimated 303,000 maternal deaths occurred globally in 2015, yielding an overall MMR of 216 (207–249) maternal deaths per 100,000 live births. The global adult life-time risk of maternal mortality (i.e. the probability that a 15 years old woman will die eventually from a maternal cause) is approximately 1 in 180 for the year 2015. For the purpose of categorization, MMR is considered to be high if it is 300–499, very high if it is 500–999 and extremely high if it is ≥1000 maternal deaths per 100,000 live births (1).

The overall MMR in developing regions is 239 (229–275), which is roughly 20 times higher than that of developed regions, where it is just 12 (11–14). Sub-Saharan Africa has a very high MMR with a point estimate of 546. Three regions – Oceania (187); South Asia (176); and South-East Asia (110) have moderate MMR. The remaining regions have low MMR.

Developing regions account for approximately 99 per cent (302,000) of the estimated global maternal deaths in 2015, with sub-Saharan Africa alone accounting for roughly 66 per cent (201,000), followed by South Asia (66,000) (1).

At country level, Sierra Leone is estimated to have the highest MMR at 1360 deaths per 100,000 live births in 2015. Nigeria and India together account for over one-third of all global maternal deaths in 2015, with an approximate 58,000 and 45,000 maternal deaths respectively (1).

An estimated global total of 13.6 million women have died in the 25 years between 1990 and 2015 due to maternal causes. Over the course of time, however, the world has made steady progress in reducing maternal mortality, reducing MMR by 44 per cent, and reducing the lifetime risk of maternal deaths from 1 in 73 to 1 in 180 (1).

A woman is most vulnerable at the post-partum period. About 50–70 per cent maternal deaths occur in the post-partum period of which 45 per cent deaths occur in the first 24 hours after delivery and more than two-thirds during the first week. Between 11–17 per cent of maternal deaths occur during childbirth itself (72).

Maternal mortality ratios strongly reflect the overall effectiveness of health systems, which in many low-income developing countries suffer from weak administrative, technical and logistical capacity, inadequate financial investment and a lack of skilled health personnel. Scaling up key interventions – for example, increasing the number of births attended by skilled health personnel, providing access to emergency obstetric care when necessary and providing post-natal care for mothers and babies – could sharply reduce both maternal and neonatal deaths. Enhancing women's access to family planning, adequate nutrition, improved water and sanitation facilities and affordable basic health care protection from abuse, violence, discrimination, empowerment of women, greater involvement of men in maternal and child care, would lower mortality rates further still. These are not impossible, impractical actions, but proven, cost-effective provisions that women of reproductive age have a right to expect.
The low status of women in the society coupled with their low literacy levels prevent the women from taking antenatal care even if services are available. Most deliveries take place at home without the services of the trained midwifery personnel. There is an inverse relationship between lifetime risk of maternal death and the availability of the trained health worker during pregnancy and at the time of delivery. The lifetime chances of maternal death in the world in 2015 as a whole is about 1 in 180. It varies from region to region and from country to country. In the least developed countries the chances are about 1 in 41, in the developing countries about 1 in 220 and in the industrialized countries about 1 in 3,300. In sub-Saharan Region the chances are very high - about 1 in 37 pregnancies (73).

It is a tragic situation as these deaths are not caused by disease but occurred during or after a natural process. It is one of the leading cause of death for women of reproductive age in many parts of the world. Most maternal deaths and pregnancy complications can be prevented if pregnant women have access to good-quality antenatal, natal and postnatal care, and if certain harmful birth practices are avoided. Estimates of antenatal care coverage, deliveries conducted by skilled personnel, lifetime risk of maternal death and maternal mortality ratio in some developing and developed countries are shown in Table 13.

Maternal health, however, goes beyond the survival of pregnant women and mothers. For every woman who dies from causes related to pregnancy or childbirth, it is estimated that there are 20 others who suffer pregnancy-related illness or experience other severe consequences. The number is striking: An estimated 10 million women annually who survive their pregnancies experience such adverse outcomes.

Causes

Maternal deaths mostly occur from the third trimester to the first week after birth (with the exception of deaths due to complications of abortion). Studies show that mortality risks for mothers are particularly elevated within the first two days after birth. Most maternal deaths are related to obstetric complications - including postpartum haemorrhage, infections, eclampsia and prolonged or obstructed labour - and complications of abortion. Most of these direct causes of maternal mortality can be readily addressed if skilled health personnel are on hand and key drugs, equipment and referral facilities are available.

About 80 per cent of maternal deaths are due to direct causes i.e. obstetric complications of pregnancy, labour and puerperium to interventions or incorrect treatment. As shown in Fig. 10 the single most common cause-accounting for a quarter of all maternal deaths is obstetric haemorrhage, generally occurring postpartum which can lead to death very rapidly in the absence of prompt life-saving care.

Source: (1, 74)
Puerperal infections, often the consequence of poor hygiene during delivery, or untreated reproductive tract infections account for about 15% of maternal mortality. Such infections can be easily prevented. Hypertensive disorders of pregnancy, particularly eclampsia (convulsions), result in about 13% of all maternal deaths. They can be prevented through careful monitoring during pregnancy and treatment with relatively simple anticonvulsant drugs in cases of eclampsia.

Of the estimated 210 million pregnancies that occur every year, about 42 million end in induced abortion, of which only approximately 60 per cent are carried out under safe conditions. More than 20 million induced abortions each year are performed by people lacking the necessary skills or in an environment lacking the minimal medical standards, or both.

Around 8% of maternal deaths occur as a result of prolonged or obstructed labour. Other direct causes include ectopic pregnancies, embolism and deaths related to interventions. Around 20 per cent of maternal deaths are due to indirect causes, that is, the result of pre-existing diseases or disease that developed during pregnancy, which are not due to direct obstetric cause but are aggravated by the physiological effect of pregnancy. One of the most significant is anaemia, which can cause death. Maternal anaemia affects about half of all pregnant women. Pregnant adolescents are more prone to anaemia than older women, and they often receive less care. Infectious diseases such as malaria, and intestinal parasites can exacerbate anaemia, as can poor quality diet - all of which heighten vulnerability to maternal death. Severe anaemia contributes to the risk of death in cases of haemorrhage. Other important causes of indirect death are hepatitis, cardiovascular diseases, diseases of the endocrine and metabolic system and infections such as tuberculosis, malaria and increasingly HIV/AIDS (73). Each year, approximately 50 million women living in malaria-endemic countries throughout the world become pregnant. Around 10,000 of these women die as a result of malaria (75).

Social correlates

A number of social factors influence maternal mortality. The important ones are: (a) Women's age: The optimal child-bearing years are between the ages of 20 and 30 years. The further away from this age range, the greater the risks of a woman dying from pregnancy and childbirth. (b) Birth Interval: Short birth intervals are associated with an increased risk of maternal mortality. (c) Parity: High parity contributes to high maternal mortality.

Not only are these three variables interrelated, but there are also other factors which are involved, e.g., economic circumstances, cultural practices and beliefs, nutritional status, environmental conditions and violence against women. The social factors often precede the medical causes and make pregnancy and child-birth a risky venture.

Global Strategy for Women's, Children's and Adolescent's Health 2016-2030

The Global Strategy for Women's, Children's and Adolescent's Health, 2016-2030 was launched in the year 2015 with a vision to have by 2030, a "world in which every woman, child and adolescent in every setting realize their rights to physical and mental health and well-being, has social and economic opportunities, and is able to participate fully in shaping prosperous and sustainable society" (76). The strategy is a road map for the post-2015 agenda as described by the Sustainable Development Goals and seeks to end all preventable deaths of women, children and adolescents and create an environment in which these groups not only survive, but thrive, and see their environments, health and wellbeing transformed. The global strategy goals of SURVIVE, THRIVE and TRANSFORM and the targets to be achieved by 2030 are as follows (76):

**SURVIVE**

End preventable deaths
- Reduce global maternal mortality to less than 70 per 100,000 live births
- Reduce newborn mortality to at least as low as 12 per 1000 live births in every country
- Reduce under-5 mortality to at least as low as 25 per 1000 live births in every country
- End epidemics of HIV, tuberculosis, malaria, neglected tropical diseases and other communicable diseases
- Reduce by one third premature mortality from non-communicable diseases and promote mental health and well-being

**THRIVE**

Ensure health and well-being
- End all forms of malnutrition, and address the nutritional needs of adolescent girls, pregnant and lactating women and children
- Ensure universal access to sexual and reproductive health-care services (including for family planning) and rights
- Ensure that all girls and boys have access to good quality early childhood development
- Substantially reduce pollution-related deaths and illnesses
- Achieve universal health coverage including financial risk protection and access to quality essential services, medicines and vaccines

**TRANSFORM**

Expand enabling environments
- Eradicate extreme poverty
- Ensure that all girls and boys complete free, equitable and good quality primary and secondary education
- Eliminate all harmful practices and all discrimination and violence against women and girls
- Achieve universal and equitable access to safe and affordable drinking water, and to adequate sanitation and hygiene
- Enhance scientific research, upgrade technological capabilities and encourage innovation
- Provide legal identity for all, including birth registration
- Enhance the global partnership for sustainable development.

**INDIA**

Despite significant improvements in maternal health over the last decade or so, which is evident in the reductions in
maternal mortality in the country, an estimated 44,000 mothers continue to die every year due to causes related to pregnancy, childbirth and the post-partum period. The major medical causes of these deaths are haemorrhage, sepsis, abortion, hypertensive disorders, obstructed labor and other causes including anaemia. A host of socio-economic-cultural determinants like illiteracy, low socio-economic status, early age of marriage, low level of women's empowerment, traditional preference for home deliveries and other factors contribute to the delays leading to these deaths.

From year 2000 onwards, SRS (Central registration system) included a new method called the “RHIME” or Representative, Re-sampled, Routine Household Interview of Mortality with Medical Evaluation. This is an enhanced form of “verbal autopsy” which is the key feature of a prospective study of 1 million deaths within the SRS. RHIME include random re-sampling of field-work by an independent team for maintaining quality of data. For comparability with WHO estimates for India and for other countries, the WHO's “Global Burden of Disease” categorization of maternal deaths have been used, which includes various categories with their ICD-10 codes such as haeorrhage, sepsis, hypertensive disorder, obstructed labour, abortion, and other conditions.

The SRS report has been grouped into three categories: (a) EAG states of Bihar and Jharkhand, Madhya Pradesh and Chhattisgarh, Odisha, Rajasthan, Uttar Pradesh and Uttarakhand and Assam. These states have high mortality indicators; (b) This category includes southern states of Andhra Pradesh, Karnataka, Kerala and Tamil Nadu. These states have comparatively better health indicators; (c) The remaining states have been classified as others (77).

Table 14 shows live births, maternal deaths, maternal mortality ratio in India by states during 2014–2016, special survey of deaths using RHIME. During this period the life-time risk of maternal death of women in the age group 15–49 has been reported to be 0.3 per cent. This is substantially higher for women in the category EAG states and Assam (0.6 per cent) compared to women in the category southern (0.2 per cent) or in the “other” states (0.2 per cent).

India is among those countries which have a high maternal mortality ratio. According to the estimates the MMR has reduced from 167 per lakh live births in 2011–13 to 130 per lakh live births in 2014–16, a reduction of 22 points per year. States of Kerala, Maharashtra, Andhra Pradesh, Gujarat and Tamil Nadu have already achieved the goal of a MMR of 100 per lakh live births. In EAG and Assam category of states, MMR is about 237 per lakh live births, with Assam on top (237) and Uttar Pradesh (201), Rajasthan (199), Odisha (180), Madhya Pradesh (173) closely following. Assam, Madhya Pradesh and Rajasthan have shown an acceleration in reduction in last three years (77).

The age distribution of maternal and non-maternal deaths from the 2014-2016 Special Survey of Deaths are given in Table 15. It shows that more than two-thirds of the maternal deaths are of women in age group 20-34 years. In contrast, non-maternal deaths are more evenly distributed over the reproductive age span of 15-49 years.

**Causes**

The major causes of maternal mortality according to the 2001-2003 SRS survey are haemorrhage (38 per cent), sepsis (11 per cent), hypertension (5 per cent), obstructed labour (5 per cent), abortion (8 per cent) and other conditions (34 per cent). Anaemia (19 per cent) is not only the leading cause of death but also an aggravating factor in haemorrhage, sepsis and toxoaemia. Illegal abortions are also one of the leading causes of maternal death. That this should continue despite MTP facilities points to the need for wider dissemination of information about these facilities. Induced abortions also point to a large unmet need for contraceptives, as with each pregnancy the woman faces increased risk of death. The percentage distribution of causes of maternal deaths during the year 2001-2003 are as shown in Fig. 11.

Newer approaches such as “risk approach” and primary health care are steps in the right direction to reduce maternal mortality and morbidity. Despite best antenatal care, some women may develop complications without warning signs and require emergency care. Essential obstetric care and establishment of first referral units (FRUs) for emergency obstetric care is, therefore, a high priority under the safe motherhood component of Reproductive and Child Health Programme. Janani Suraksha Yojna, Janani Shishu Suraksha Karyakram, establishment of MCH wings and mother and child tracking system; and RMNCH+A are key strategies to accelerate the pace of decline of MMR. Equally important is an attack on social and cultural factors (e.g., ignorance, low levels of female literacy, prejudices inherent in the socio-cultural milieu, low levels of nutrition and poor environmental sanitation). It calls for socio-economic development of the community through active community involvement.

**National maternal health care indicators**

The estimates of maternal mortality can only be used as a rough indicator of maternal health situation in any given country. Hence indicators such as antenatal check-up, institutional delivery and delivery by trained personnel etc. are used to assess the maternal health status. These indicators also reflect the status of the ongoing programme interventions and the situation of maternal health (58). Table 17 shows the national average of key indicators as per NFHS-4 conducted in India (58).

**Preventive and social measures**

High maternal mortality reflects not only in inadequacy of health care services for mothers, but also a low standard of living and socio-economic status of the community. In the world as a whole, the problem of maternal mortality is principally one of applying existing obstetric knowledge through antenatal, intranatal and postnatal services rather...

than developing new skills. Any attempt to lower MMR must take into consideration the following measures:

1. Early registration of pregnancy;
2. At least four antenatal check-ups;
3. Dietary supplementation, including correction of anaemia;
4. Prevention of infection and haemorrhage during puerperium;
5. Prevention of complications, e.g., eclampsia, malpresentations, ruptured uterus;
6. Treatment of medical conditions, e.g., hypertension, diabetes, tuberculosis, etc;
7. Anti-malaria and tetanus prophylaxis;
8. Clean delivery practice;
9. In India, a large number of maternal deaths could be prevented with the help of trained village level health workers;
10. Institutional deliveries for women with bad obstetric history and risk factors;
11. Promotion of family planning – to control the number of children to not more than two, and spacing of births;
12. Identification of every maternal death, and searching for its cause; and
13. Safe abortion services

MORTALITY IN INFANCY AND CHILDHOOD

Mortality rates are good indicators to measure the level of health and health care in different countries. They also help in assessing the overall socio-economic development of a country and correlate well with certain economic variables such as GNP. Medical and social progress have substantially reduced mortality in childhood.

It has become customary to consider mortality in and around infancy in a number of time periods convenient from both the analytical and programmatic point of view as under:

a. perinatal period
b. early neonatal period
c. late neonatal period
d. neonatal period
e. post neonatal period

These are as illustrated in Fig. 12.

FOETAL DEATH: Foetal death is death prior to the complete expulsion or extraction from its mother of a product of conception, irrespective of the duration of pregnancy; the death is indicated by the fact that after such separation the foetus does not breathe or show any other evidence of life, such as beating of the heart, pulsation of the umbilical cord, or definite movement of voluntary muscles (79). Defined variously as death after the 20th or 28th week of gestation (the definition of length of gestation varies between countries).

Some observers have expressed the view that vital statistical reports are less reliable on foetal deaths occurring at 20–27 weeks than on those occurring after 28 completed

Mortality in and around infancy

weeks, and have preferred to analyze the data separately for the two intervals. Stillbirths are seldom reported in developing countries.

Because of the above difficulties WHO has recommended that within any country the term “stillbirth” be applied to a foetus born dead, and weighing over 500 g – the birth weight most frequently associated with a gestation period of 22 weeks. But for international comparison, however, they suggested a boundary of 1000 g or more, which is more frequently associated with a gestation period of 28 weeks.

STILLBIRTH RATE

The most widespread use of the term is, “death of a foetus weighing 1000 g (this is equivalent to 28 weeks of gestation) or more” occurring during one year in every 1000 total births (live births plus stillbirths). Stillbirth rate is given by the formula:

\[
\text{Stillbirth rate} = \frac{\text{Foetal deaths weighing over 1000 g at birth during the year}}{\text{Total live + stillbirths weighing over 1000 g at birth during the year}} \times 1000
\]

It is a frequent occurrence in the developing countries. Its prevention involves the detection and treatment of infectious pathology in the course of pregnancy as well as of high blood pressure and its complications, Rh incompatibility, diabetes and premature rupture of the membrane. Some causes are difficult or impossible to eliminate, such as multiple pregnancies, cord anomalies, foetal malformations, placenta anomalies.

Approximately 2.5 million babies were stillborn in the year 2016 worldwide (80). In India, the SRS estimates for the year 2016 for the whole country is about 3 per 1000 total births (4 for the rural and 2 for the urban areas). Among the bigger states, the highest level of stillbirths has been estimated for Himachal Pradesh (24). Table 18 shows the statewise break-up of stillbirth rate.

Source: (81)

The estimates provided by Lancet Stillbirth Series for India is 22 per 1000 live births for the year 2009. This estimate is being used as a target-setting exercise by India Newborn Action Plan (launched in June 2014). With the current level of average annual rate of reduction, which is less than 1 per cent, India is expected to reach SBR of 19 per 1000 live births by 2030 (82).

PERINATAL MORTALITY RATE

As currently defined, the term “perinatal mortality” includes both late foetal deaths (stillbirths) and early neonatal deaths. The Eighth Revision of the International Classification of Diseases (ICD) defined the “perinatal period” as lasting from the 28th week of gestation to the seventh day after birth. The Tenth Revision (1993) of ICD added that:

1) Babies chosen for inclusion in perinatal statistics (this means late foetal deaths, live births and early neonatal deaths) should be those above a minimum birth weight, i.e., 1000 g at birth (A birth weight of 1000 g is considered equivalent to gestational age of 28 weeks);
2) if the birth weight is not available, a gestation period of at least 28 weeks should be used; and
3) where (i) and (ii) are not available, body length (crown to heel) of at least 35 cm should be used.

But the preferred criterion is birth weight.

The Conference for the Tenth Revision (ICD-10) made no changes to these definitions.

DEFINITIONS (83)

The WHO’s definition, more appropriate in nations with well established vital records of stillbirths is as follows:

1. Babies chosen for inclusion in perinatal statistics (this means late foetal deaths, live births and early neonatal deaths) should be those above a minimum birth weight, i.e., 1000 g at birth (A birth weight of 1000 g is considered equivalent to gestational age of 28 weeks);
2. if the birth weight is not available, a gestation period of at least 28 weeks should be used; and
3. where (i) and (ii) are not available, body length (crown to heel) of at least 35 cm should be used.

But the preferred criterion is birth weight.

The Conference for the Tenth Revision (ICD-10) made no changes to these definitions.

DEFINITIONS (83)

The WHO’s definition, more appropriate in nations with well established vital records of stillbirths is as follows:
Late foetal deaths (28 weeks gestation and more) + early neonatal deaths (first week) in one year

PMR = \frac{\text{Live births} + \text{late foetal deaths (28 weeks gestation and more) in the same year}}{\text{Live births + late foetal deaths (28 weeks gestation and more) in one year}} \times 1000

The WHO's definition, more appropriate in nations with less well established vital records, is:

\[ \frac{\text{Late foetal deaths (28 weeks + of gestation) } + \text{postnatal deaths (first week) in a year}}{\text{Live births in a year}} \times 1000 \]

There is a difference in denominator of the perinatal mortality rate defined by the WHO and industrially developed nations. This makes international comparisons difficult.

**International comparisons**

For international comparisons, the WHO Expert Committee on the Prevention of Perinatal Mortality and Morbidity (1970) recommended a more precise formulation: “late foetal and early neonatal deaths weighing over 1000 g at birth, expressed as a ratio per 1000 live births weighing over 1000 g at birth”. It is calculated as:

\[ \frac{\text{Late foetal and early neonatal deaths weighing over 1000 g at birth}}{\text{Live births + late foetal deaths (28 weeks gestation and more)}} \times 1000 \]

**Why perinatal mortality rate?**

With the decline of infant mortality rate to low levels in many developed countries, perinatal mortality rate has assumed greater significance as a yardstick of obstetric and paediatric care before and around the time of birth.

First, two types of death rate i.e., stillbirths and deaths under the first week of life are combined in perinatal mortality rate because the factors responsible for these two types of deaths are often similar, being those operating before and around the time of birth. Secondly, a proportion of deaths which occur after birth are incorrectly registered as stillbirths, thereby inflating the stillbirth rate and lowering the neonatal death rate. The perinatal mortality rate, being a combination of stillbirths and early neonatal deaths, is not influenced by this error, by removing from consideration the dividing line between a stillbirth and a live birth with death shortly after birth.

Although perinatal period occupies less than 0.5 per cent (less than 168 hours) of the average life span, there are more deaths within this period than during the next 30-40 years of life in many developing countries. The value of perinatal mortality rate is that it gives a good indication of the extent of pregnancy wastage as well as the quality and quantity of health care available to the mother and the newborn. It reflects the results of maternity care more clearly than the neonatal death rate.

**Incidence**

Perinatal mortality is a problem of serious dimensions in all countries. It now accounts for about 90 per cent of all foetal and infant mortality in the developed countries. In India, stillbirths are seldom registered. Consequently, most studies on perinatal mortality in this country are hospital-based. The SRS estimates for perinatal mortality rate in India for the year 2016 was about 23 per 1000 live births and stillbirths, with about 26 for rural areas and 14 for the urban areas. The statewise perinatal mortality rate is shown in Table 18.

In developed countries, perinatal mortality rates have gradually declined during the past decades due to improved obstetric and perinatal technologies.

**Social and biological variables**

A number of social and biological factors are known to be associated with perinatal mortality. The degree to which these factors influence perinatal mortality varies from country to country. Many of these factors also endanger the life of the mother, causing high maternal mortality. An appreciation of these factors (at-risk factors) will certainly make the greatest impact on reducing perinatal mortality. The overall risk is increased in the following categories:

1. Low socio-economic status; (2) High maternal age (35 years or more); (3) Low maternal age (under 16 years); (4) High parity (fifth and subsequent pregnancies, especially with short intervals between pregnancies); (5) Heavy smoking (10 or more cigarettes daily); (6) Maternal height—short stature (as compared with average for locality); (7) Poor past obstetric history (one or more previous stillbirths and neonatal deaths, one or more premature live-born infants); (8) Malnutrition and severe anaemia; and (9) Multiple pregnancy.

For further details see page 624 under “factors affecting infant mortality”.

**Causes of perinatal mortality**

About two-thirds of all perinatal deaths occur among infants with less than 2500 g birth weight. The causes involve one or more complications in the mother during pregnancy or labour, in the placenta or in the foetus or neonate.

**Main causes:** The main causes of death are intrauterine and birth asphyxia, low birth weight, birth trauma, and intrauterine or neonatal infections. The various causes of perinatal mortality may be grouped as below:

(a) **Antenatal causes**

1. Maternal diseases: hypertension, cardiovascular diseases, diabetes, tuberculosis, anaemia
2. Pelvic diseases: uterine myomas, endometriosis, ovarian tumours
3. Anatomical defects: uterine anomalies, incompetent cervix
4. Endocrine defects: uterine anomalies, incompetence, uterine preparation
5. Blood incompatibilities
6. Malnutrition
7. Toxaemias of pregnancy
8. Antepartum haemorrhages
9. Congenital defects
10. Advanced maternal age

(b) **Intrapartal causes**

1. Birth injuries
2. Asphyxia
3. Prolonged effort time
4. Obstetric complications

(c) **Postnatal causes**

1. Prematurity
2. Respiratory distress syndrome
Prevention of perinatal mortality

Interventions for the reduction of perinatal mortality

Measures to reduce perinatal mortality rates are essential to accelerate the declining trend in neonatal and infant mortality rates. For further details, refer to Table 21.

International certificate of perinatal death

For international comparability, the 9th (1975) Revision of International Classification of Diseases (ICD-9) recommended a special certificate of cause of perinatal death. The ICD also has a list of 100 causes (the “P” list) for tabulation of perinatal morbidity and mortality (31).

Prevention of perinatal mortality

See page 625 under Preventive & Social Measures.

NEONATAL MORTALITY RATE

Neonatal deaths are deaths occurring during the neonatal period, commencing at birth and ending 28 completed days after birth. Neonatal mortality rate is the number of neonatal deaths in a given year per 1000 live births in that year.

The neonatal mortality rate is tabulated as:

\[
\text{Neonatal mortality rate} = \frac{\text{Number of deaths of children under 28 days of age in a year}}{\text{Total live births in the same year}} \times 1000
\]

Causes of neonatal mortality

The main causes of neonatal death globally are as shown in Fig 13.

No woman should die giving life. Nor should any mother endure pregnancy and childbirth, only to go through the agony of having her child born dead or watching the baby die minutes after birth. Yet for countless women around the world, this scenario remains a tragic reality. The first 28 days of life – the neonatal period, is the most vulnerable time for a child's survival. In order to continue to accelerate progress in under-five mortality, focusing on newborns is critical.

Neonatal mortality rates of babies born to mothers with no education are nearly twice as high as those of babies born to mothers with secondary education or higher. The family's wealth and rural/urban residence also remain powerful determinant of inequities in neonatal mortality. Ending child marriage, reducing adolescent pregnancy and extending birth intervals are crucial to reducing the risk of newborn mortality.

Direct causes of newborn death vary from region to region. In general, the proportions of deaths attributed to prematurity and congenital disorders increase as the neonatal mortality rate decreases, while the proportions caused by infections, asphyxia, diarrhoea and tetanus decline as care improves. Patterns of low birth weight vary considerably between countries. Babies with a low birth weight are especially vulnerable to the hazards of the first hours and days of life, particularly if they are premature. Majority of low-birth-weight babies are not actually premature but have suffered from in utero growth restriction, usually because of the mother's poor health. These babies too are at increased risk of death.

The main causes of neonatal death are intrinsically linked to the health of the mother and the care she receives before, during and immediately after giving birth. Asphyxia and birth injuries usually result from poorly managed labour and delivery, and lack of access to obstetric services. Many neonatal infections, such as tetanus and congenital syphilis, can be prevented by care during pregnancy and childbirth. Inadequate calorie or micronutrient intake also results in poorer pregnancy outcomes. It has been argued that nearly three quarters of all neonatal deaths could be prevented if women were adequately nourished and received appropriate care during pregnancy, childbirth and in the postnatal period.

However, neonatal mortality is the most difficult part of infant mortality to alter, because of the endogenous factors which are not sensitive to improvements in environmental conditions. Neonatal mortality is greater in boys throughout the world, because newborn boys are biologically more fragile than girls.

Incidence

Each year, about 2.7 million newborns die before they are 4 weeks old and half of them die in their first 24 hours. 98 per cent of these deaths occur in developing countries.
Newborn deaths now contribute to about 45 per cent of all deaths in children under five years of age globally, and more than half of infant mortality. About 1 million babies die every year on the day of their birth and close to 2 million die in the first week of their life (86). Rates are highest in sub-Saharan Africa and Asia. Two-thirds of newborn deaths occur in WHO Region of Africa (31 per cent) and South East Asia (30 per cent). The gap between rich and poor countries is widening – neonatal mortality is now 6.5 times lower in high income countries than in other countries. The lifetime risk for a woman to lose a newborn baby is now 1 in 5 in Africa, compared to 1 in 125 in more developed countries (86).

India

In India the SRS estimates for the year 2016 is about 18 per 1000 live births in early-neonatal period (0-7 days), with about 21 for rural areas and 11 for urban areas. Table 19 shows the early neonatal mortality rate and percentage share of early neonatal mortality to infant deaths in the country and the major states. Among the bigger states, Kerala (4) and Madhya Pradesh and Odisha (24) are the two extremes. The percentage of early neonatal deaths to the total infant deaths during the year 2016, at the national level, has been 53.2, and it varied from 54.8 in rural areas to 45.8 in urban areas. In most of the states rural proportion is relatively higher than the urban proportion. Among the bigger states, the percentage for total varied from 40.5 in Kerala to 62.9 in Uttarakhand.

Table 20 shows the neonatal mortality rate in the country and the percentage of neonatal deaths to infant deaths for the year 2016, both at the national and state levels. At the national level, the neonatal mortality rate was 24 and ranged from 14 in urban areas to 27 in rural areas. Among the bigger states neonatal mortality ranges from 32 in Odisha and Madhya Pradesh to 6 in Kerala. The percentage of neonatal deaths to total infant deaths was 68.8 per cent at the national level and varied from 60.4 per cent in urban areas to 70.7 per cent in rural areas. Among the bigger states Uttarakhand (79.1) registered the highest percentage of neonatal deaths to infant deaths, and the lowest was in Assam (53.4).

### CAUSES OF NEONATAL DEATHS IN INDIA

The major causes of neonatal deaths are shown in Fig. 14.

It is estimated that 40 per cent of all stillbirths and neonatal deaths take place during labour and the day of birth, and about 75 per cent of total neonatal deaths occur within the first week of life. Notably half of all the maternal deaths also take place in this period (82).

India accounts for 40 per cent of the global burden of low birth weight babies with 7.5 million babies (or about 30 per cent of the country's total annual live births) being born with a birth weight less than 2500 grams. Of these 7.5 million babies, about 60 per cent are born at term after foetal
growth retardation, while the remaining 40 per cent are born preterm, constituting one fourth of global burden of preterm births. Preterm babies in addition to being at a higher risk of neonatal mortality, are at an increased risk of post-neonatal mortality, stunting, and long-term neurodevelopmental impairment during childhood (82).

**Interventions for the reduction of neonatal mortality**

Measures to reduce neonatal mortality rates and to improve newborn health are enumerated in Table 21.

**POST-NEONATAL MORTALITY RATE**

Deaths occurring from 28 days of life to under one year are called “post-neonatal deaths”. The post-neonatal death rate is defined as: “the ratio of post-neonatal deaths in a given year to the total number of live births in the same year; usually expressed as a rate per 1000”(87).

The post-neonatal mortality rate is tabulated as:

\[
\frac{\text{Number of deaths of children between 28 days and one year of age in a given year}}{\text{Total live births in the same year}} \times 1000
\]

Whereas neonatal mortality is dominated by endogenous factors, post-neonatal mortality is dominated by exogenous (e.g., environmental and social) factors. Diarrhoea and respiratory infections are the main causes of death during the post-neonatal period. Malnutrition is an additional factor, reinforcing the adverse effects of the infections. In the developed countries, the main cause of post-neonatal mortality is congenital anomalies. Studies show that post-neonatal mortality increases steadily with birth order, and that infants born into already large families run a higher risk of death from infectious diseases.

Source: (89)
In some areas of South East Asia (including India), during the post-neonatal period girls die more frequently than boys. This is attributed to neglect of the female children in terms of nutrition and health care (88).

The SRS estimates for post-neonatal mortality rate in India for the year 2016 is about 11 per 1000 live births for the whole country, and 11 for rural areas and 9 for the urban areas. The state-wise break-up is shown in Table 22.

**INFANT MORTALITY RATE**

Infant mortality rate (IMR) is defined as "the ratio of infant deaths registered in a given year to the total number of live births registered in the same year; usually expressed as a rate per 1000 live births" (90). It is given by the formula:

\[
IMR = \frac{\text{Number of deaths of children less than 1 year of age in a year}}{\text{Number of live births in the same year}} \times 1000
\]

IMR is universally regarded not only as a most important indicator of the health status of a community but also of the level of living of people in general, and effectiveness of MCH services in particular. Infant mortality is given a separate treatment by demographers because: (a) infant mortality is the largest single age-category of mortality; (b) deaths at this age are due to a peculiar set of diseases and conditions to which the adult population is less exposed or less vulnerable; (c) infant mortality is affected rather quickly and directly by specific health programmes and hence may change more rapidly than the general death rate.

**International comparisons**

During the past decades, there has been a steady decline in infant mortality (Table 23).

Source: (85)

There are wide variations between countries or regions in the levels of infant mortality. The world average of IMR for 2016 has been estimated at about 29.4 per 1000 live births. However, IMR varies from 5 per 1000 live births in the developed countries to 56 per 1000 live births in the sub-Saharan countries. The average in the South Asian countries was 42 per 1000 live births. Although infant mortality declined significantly, the drop was greatest for the developed countries and lowest for the least developed countries. The developed world had a much greater reduction in infant mortality compared to child mortality, while in the developing world the situation was reverse (85).

The IMRs in industrialized countries were around 200 or even more some 150 years ago. Even at the beginning of the 20th century, USA, UK, Japan, France, etc., had rates above 140 per 1000 live births. Within 50 years (1950) a spectacular fall in the rate was observed in all developed countries. By 1980s, most developed countries achieved IMR rates below 10 per 1000 live births. Demographers opine that in most developed countries, further decline in IMR would be difficult to achieve without some revolutionary advances in perinatology. Any further reduction in infant mortality in developed countries will depend upon preventing one of its principal causes, namely, congenital abnormalities.

In general, the infant mortality rates reflect the socioeconomic development of a country. Deaths during the first four weeks are largely preventable by good health care. Much of the variations between developed and developing world in death among newborn can be explained by differences in antenatal care — about half of all pregnant women in the least developed countries have no antenatal care, and 7 out of 10 babies are born without the help of a trained birth attendant. The other major factors being malnutrition and high parity of the mother, low birth weight of the baby, and congenital anomalies.

The decline in infant mortality has been attributed to: (a) improved obstetric and perinatal care, e.g., availability of oxygen, foetal monitoring during labour, improved techniques for the induction of labour (b) improvement in the quality of life, that is, economic and social progress (c) better control of communicable diseases, e.g., immunization and oral rehydration (d) advances in chemotherapy, antibiotics and insecticides (e) better nutrition, e.g., emphasis on breast feeding, and (f) family planning, e.g., birth spacing.

In the industrial world, the dominant factor in the decline of infant mortality was economic and social progress (i.e.,
quality of life), with medical services playing secondary role. On the other hand, in most of the developing countries, this pattern has been almost turned upside down. That is, medical services (e.g., mass control of disease, immunization, antibiotics and insecticides) have made the major impact, with social and economic progress taking the supporting role. Therefore, infant mortality rates are reluctant to fall below 100 per 1000 live births in many developing countries. It is now conceded that only socio-economic development can re-accelerate the progress and lead to further significant fall in infant deaths.

Infant mortality in India

India is still among high infant mortality rate countries (38 in the year 2016). IMR has declined slowly from 204 during 1911-15, to 129 per 1000 live births in 1970 and remained static at around 127 for many years, and then declined a bit once again to 114 in 1980 and coming down to 32 in the year 2017. Despite this significant decline, the rates are very high as compared to developed countries (Table 23) which are now mostly in the range of 3-7 per 1000 live births.

India is a vast country with widely differing populations. The all-India rate masks variations that exist among sub-groups of the population. An examination of state-wise IMR for the year 2016 shows a vast regional variation, with Madhya Pradesh having IMR of 47 and Kerala as low as 10 per thousand live births during the year 2016. Among the larger States Kerala, Maharashtra, Punjab, Tamil Nadu, West Bengal, Andhra Pradesh, Haryana, Karnataka, Gujarat, Himachal Pradesh, and Jharkhand have achieved IMR below the national average of 34. Within each state there is rural urban variation. A critical infant mortality belt runs through Odisha, Madhya Pradesh, Assam, Bihar, Chhattisgarh, Uttar Pradesh, and Rajasthan; all these states have infant mortality rates above the national average.

Table 24 shows infant mortality rate in major states of India.

Source : (81, 91)

Table 25 shows that Kerala has managed to surpass all the Indian states in certain important measures of social development. It has the lowest infant mortality rate, the lowest birth rate and the highest literacy rate.

### Mortality pattern

(a) Age: Deaths in the age-group 0—1 year account for 10.9 per cent of the total deaths in the country. About 67.6 per cent of infant deaths occur within the first month (neonatal period) of life. Of these, 52.0 per cent may die during the first week of birth (81). The risk of death is the greatest during the first 24-48 hours after birth. The problem is more acute in rural areas where expert obstetric care is scarce. (b) Sex: Whereas in all developed countries, male death rates are higher than female deaths, in India, after the age of one month (post-neonatal period) female deaths are invariably higher than male deaths. Social scientists have attributed this phenomenon to social factors unfavourable to females in India (92).

### Medical causes of infant mortality

The causes of infant mortality are multifactorial. The medical causes are shown in Table 26 under two subdivisions — neonatal and post-neonatal mortality.
The principal causes of infant mortality in India are low birth weight (57%), respiratory infections (17%), diarrhoeal diseases (4%), congenital malformations (5%) and cord infection (2%), birth injury (3%) and unclassified about (18%) (63). Neonatal deaths make a major contribution to infant mortality. Whereas in developing countries, the high infant mortality is mainly due to low birth weight, and the combined effects of infection (e.g., diarrhoea, respiratory infections) and malnutrition, in developed countries, it is mainly due to congenital anomalies, anoxia and hypoxia.

Factors affecting infant mortality

Infant mortality is due to the interaction of several factors in combination. They may be classified as biological, economic, and social factors.

1. BIOLOGICAL FACTORS

(a) Birth weight

Birth weight is a major determinant of infant and perinatal mortality and morbidity. Babies of low birth weight (under 2.5 kg) and high birth weight (over 4 kg) are at special risk. Virtually, all infants weighing less than 1000 g at birth succumb. One major cause of low birth weight is poor maternal nutrition — not only during pregnancy, but even before that. It has been observed that the mother who was adequately nourished during her own growing-up years has an excellent chance of delivering a normal size baby even if she has taken an inadequate diet during her pregnancy. An increase in birth weight would lower the perinatal and neonatal mortality.

(b) Age of the mother

There is a definite relationship between the age of the mother and the fate of the child. Infant mortality rates are greater when the mother is either very young (below the age of 19 years) or relatively older (over 30 years). Very young mothers also tend to be poorer and less educated (93).

(c) Birth order

The live births are classified according to their order of rank. The highest mortality is found among first born, and the lowest among those born second. The risk of infant mortality escalates after the third birth. The fate of the 5th and later children is always worse than the fate of the 3rd child. Infant mortality from nutritional deficiencies are 3-4 times higher for infants born with fifth or higher birth order compared to the first three. These deaths occur mostly in post-neonatal period.

(d) Birth spacing

Repeated pregnancies exert a great influence on infant mortality. They cause malnutrition and anaemia in the mother, again predispose to low birth weight, which results in higher infant death. The mother who becomes pregnant again too early and whose youngest baby is displaced from the breast, and prematurely weaned — that baby is more prone to develop (a) protein energy malnutrition (b) diarrhoea and dehydration, both of which cause an increased mortality in infants and young children. The Khanna Study in India showed that IMR was highest for infants born after an interval of one year, lower for those born after an interval of 2-3 years, and lowest for those born after an interval of 4 years (94). A WHO study in rural India also showed similar findings (95). Evidence from the World Fertility Survey — the largest survey into human behaviour ever undertaken — suggests that the risks to life for babies born within a year of each other is 2-4 times higher than for babies born more than 2 years apart. Wider spacing of births curtails infant mortality, and is considered as important part of health care as immunization (96).

(e) Multiple births

Infants born in multiple births face a greater risk of death than do those in single births due in large part to the greater frequency of low birth weight among the former.

(f) Family size

Studies show the infant mortality increases with family size. The number of episodes of infectious diarrhoea, prevalence of malnutrition, and severe respiratory infections have been found to increase with family size. Besides the frequency of disease, the duration of illness is also affected by the family size. It was found that the duration of illness is much longer in families with 3 or more children. Deprivation of maternal care is also found in large families. Fewer children would mean better maternal care, a better share of family resources, less morbidity and greatly decreased infant mortality.

(g) High fertility

Fertility is one of the most important factors that influence infant mortality. High fertility and high infant mortality go together.

2. ECONOMIC FACTORS

One of the most important variables affecting infant mortality rates, both directly and indirectly, is socio-economic status. The availability and quality of health care and the nature of the child’s environment are closely related to socio-economic status. Statistics reveal that infant mortality rates are highest in the slums and lowest in the richer residential localities. Major improvements in health status and a decrease in infant mortality require continuing socio-economic development, including provision of health services.

3. CULTURAL AND SOCIAL FACTORS

(a) Breast-feeding

Infant health is related to breast feeding because of the nutritional content and natural immunizing agents contained in breast milk, at least for fully breast-fed infants. Early weaning and bottle-fed infants living under poor hygienic conditions are more prone to die than the breast-fed infants living under similar conditions.

(b) Religion and caste

The differences are attributed to socio-cultural patterns of living, involving age-old habits, customs, traditions affecting cleanliness, eating, clothing, child care and almost every detail of daily living.
(c) Early marriages
The baby of teen-age mother has the highest risk for neonatal and post-neonatal mortality.

(d) Sex of the child
In most parts of India, female infants receive far less attention than males. This is especially the case, where there are already several female children. In many families, the birth of a female child is unwelcome. Statistics show that female infant mortality is higher than the male infant mortality. But when the total infant mortality is split into neonatal and postneonatal deaths, the picture gets reversed, i.e., neonatal death rate is higher for males than for female infants; post-neonatal death rate is higher for female infants than male infants (92).

(e) Quality of mothering
The art of child care has to be learnt. Even in conditions of extreme poverty, children could reasonably survive if they had an efficient mother. It is the "quality of mothering" that helps to reduce infant mortality.

(f) Maternal education
Illiteracy is the greatest barrier to any improvement in the health conditions. Mother's education level, even within the same socio-economic class is a key determinant of their children's health. There is extensive evidence (e.g. Kerala experience) that maternal education plays a major role in the decline of infant and child mortality, presumably reflecting personal health behaviour, care and access to and use of health services. Women with schooling tend to marry later, delay child-bearing and are more likely to practice family planning. They generally have fewer children with wider spacing between births.

(g) Quality of health care
Another likely factor affecting infant mortality in contemporary India is inadequate prenatal care and infrequent attendance at delivery.

The percentage of deliveries attended by untrained persons or relatives is very high in rural India. Shortage of trained personnel like dais, midwives and health visitors is another determinant of high infant mortality in India. According to estimates only 47 per cent of the deliveries are attended by trained birth attendants.

(h) Broken families
Infant mortality tends to be high where the mother or father has died or separated.

(i) Illegitimacy
Illegitimacy is also an important factor contributing to high infant mortality rate. A child born out of wedlock is generally unwanted both by the mother as well as society. Consequently such a child does not receive the care in terms of nutrition and medical care that it needs.

(j) Brutal habits and customs
Certain age-old customs and beliefs greatly influence infant mortality rate. These include depriving the baby of the first milk or colostrum, frequent purgation, branding the skin, application of cowdung to the cut end of umbilical cord, faulty feeding practices and early weaning.

(k) The Indigenous dai
The untrained midwife is greatly responsible for the high infant mortality in India. She is usually an illiterate person devoid of all knowledge of rules of hygiene. Her unhygienic delivery practice is an important cause of high infant mortality.

(l) Bad environmental sanitation
Infants are highly susceptible to bad environmental sanitation. Lack of safe water supply, poor housing conditions, bad drainage, overcrowding, and insect breeding, all increase the risk of infant mortality.

The fourth National Family Health Survey conducted in India during 2014-2016 provides vast information on factors associated with mortality in infancy and childhood.

Preventive and social measures
There is no single specific health programme or a single set of action that can reduce IMR. Since the etiology of infant and perinatal mortality is multifactorial, nothing less than a multipronged approach will reduce infant and perinatal mortality. Under ideal conditions of Social Welfare, no baby should die, except possibly the few who are born with serious handicaps such as congenital abnormalities or disorders originating in uterine life. The measures needed to achieve reduction of infant mortality comprise the following:

1. Prenatal nutrition
The risk of death begins to appear even before birth, if the mother is malnourished. Therefore, the very first need is to improve the state of maternal nutrition. There is mounting evidence that the addition of even a small amount of extra food by way of supplementation to the mother's basic diet goes a long way in improving the birth weight of babies. In a controlled study in India, poor women were fed an additional 500 kcals and 10 g of protein during the last 4 weeks of pregnancy. Their infants' birth weights were on an average 300 g above those infants born to the control group (97, 98). This points to the need for food supplementation programmes during pregnancy. ICDS (Integrated Child Development Services) in India is active in this field.

2. Prevention of Infection
The major causes of sickness and death of children in India are infectious diseases, many of which are preventable by immunization, as for example, neonatal tetanus. A large number of cases of EPI targeted diseases are reported each year. The Universal Immunization Programme launched in 1985 aims at providing protection to all the expectant mothers and children against 9 vaccine preventable diseases, and thereby ensure greater child survival.

3. Breast-feeding
The most effective measure for lowering infant mortality is to promote breast-feeding, which is a safeguard against gastrointestinal and respiratory infections and PEM.

4. Growth monitoring
It is a low cost technology available for reducing infant mortality. All infants should be weighed periodically (at least once a month) and their growth charts maintained. These charts help to identify children at risk of malnutrition early. Babies who do not thrive or show growth failure are given special health care to pull them on to the road—to—health. Thus systematic use of growth chart will help to promote health in children.

5. Family planning
Family limitation and spacing of births contribute substantially to lowering of infant mortality rate. The risk of death is greatly enhanced if the last child was born less than 2 years ago, and if the mother already has four or more...
given year. It thus excludes infant mortality. The rate is computed by the formula:

\[
\text{Child death rate (1-4 years)} = \frac{\text{No. of deaths of children aged 1-4 years during a year}}{\text{Total no. of children aged 1-4 years at the middle of the year}} \times 1000
\]

The child death rate is a more refined indicator of the social situation in a country than infant mortality rate. It reflects the adverse environmental health hazards (e.g., malnutrition, poor hygiene, infections and accidents), including economic, educational and cultural characteristics of the family. Mortality in this age group no longer depends on perinatal hazards and other endogenous factors, which often cause loss of life during the first year of life.

In the age group 1-4 years, the second year is the period when the young child runs the highest risk of dying. In the developing countries, death in the second year of life commonly accounts for 50 per cent of all deaths between 1-4 years of age. After the second year, death rates decline progressively. The infectious diseases of childhood such as measles, whooping cough, diphtheria and acute respiratory infections affect mostly this age group, and can lead to high case-fatality rate in malnourished children.

Mortality rate at ages 1-4 years is about 30 in some developing countries whereas it is less than one in developed countries. The contrast is glaring. While on an average, the IMR is 10-20 times higher in developing countries than in the developed countries, the average mortality rate between the age 1-4 years is 30-50 times higher.

In India, for the year 2016, 1-4 years age crude death rate was estimated to be 1.4 per cent of total deaths. Like infant mortality, 1-4 year age mortality also shows wide state-wise variations as shown in Table 27. The states reporting rates higher than the national average are Madhya Pradesh 2.8, Haryana 1.6, Odisha 2.2, Jharkhand 1.4, Bihar 1.7, and Assam with 3.0 (81). Kerala recorded the lowest with 0.3 per cent followed by Tamil Nadu with 0.6 per cent.

The leading causes of death in 1–4 years age group in developing countries are diarrhoeal diseases and respiratory infections, closely followed by other communicable diseases such as whooping cough and measles. When combined with malnutrition these diseases have high case fatality rates. In the developed countries deaths from infectious diseases are quite rare, while accidents are the leading cause of death from the age of one year. Four groups of home accidents have been identified - (a) falls from unprotected stairs, and balconies (b) suffocation (c) burns and scalds (d) poisoning. Almost all accidents are preventable. The factors such as congenital anomalies and neoplasms are not easy to prevent or to cure. These conditions also affect children in developing countries, but their relative importance is overshadowed by infections.

**UNDER-5 MORTALITY RATE**

*(Child mortality rate)*

UNICEF defines this as the “annual number of deaths of children age under 5 years, expressed as a rate per 1000 live births.” More specifically, it measures the probability of dying between birth and exactly 5 years of age. UNICEF considers this as the best single indicator of social development and well-being rather than GNP per capita, as the former reflects income, nutrition, health care and basic education etc (100). The rate is calculated by the formula:

\[
\text{Child mortality rate} = \frac{\text{Number of deaths of children less than 5 years of age in a given year}}{\text{Number of live births in the same year}} \times 1000
\]

Around the world, remarkable progress in child survival has been made and millions of children have better survival chances than in 1990. The under-5 mortality rate fell to 39 deaths per 1000 live births in 2017, from 93 in 1990 – a 58 per cent reduction. This is equivalent to 1 in 11 children dying before reaching age 5 years in 1990, compared to 1 in 26 in 2017. In most of the SDG regions, the under-5 mortality rate was reduced by at least half since 1990. The total number of under-5 deaths dropped to 5.4 million in 2017 from 12.6 million in 1990. On average, 15,000 children died every day in 2017, as compared to 34,000 in 1990 (99).

Despite progress over the past 2 decades, millions of newborns and children die every year, mostly from preventable or treatable causes such as infectious diseases and injuries. These deaths reflect the limited access of children and communities to basic medical treatment of infectious diseases, adequate nutrition, health interventions such as vaccination, clean water and sanitation. Children face widespread regional and income disparities in their chances of survival. Sub-Saharan Africa continues to be the region with the highest under-five mortality rate in the world – 76 deaths per 1000 live births in 2017. This translates to 1 child in 13 dying before his fifth birthday - 14 times higher than the average ratio of 1 in 185 in high income countries and 20 times higher than the ratio of 1 in 263 in the region of Australia and New Zealand. In 2017, about 30 per cent under-five mortality occurred in Southern Asia. About 38 per cent of all deaths occur in least developed countries. The number of countries with gender disparities in child mortality continues to decline. On average boys are expected to have a higher probability of dying before reaching age 5 years than girls. The estimated under-5 mortality rate in 2017 was 41 deaths per 1000 live birth for boys and 37 deaths per 1000 live births for girls. In 2017, an estimated 2.9 million boys and 2.5 million girls under 5 years of age died (99).

A recent analysis showed that children in the poorest households are nearly twice likely to die before the age of 5 as those from the richest. The risk of death in rural areas is 1.5 times higher than for children in the urban areas and within urban areas children from poorer household tend to have higher mortality rates. Children of mothers who lack any education are 2.6 times more likely to die before reaching 5 years age. Poor air quality is another risk factor for child mortality (99).

Table 29 shows child mortality rate in some selected developed and developing countries.

**Causes of under-five deaths**

Understanding the causes of child mortality provides important public health insights. Of the 5.4 million deaths in children under-5, that occurred in 2017, almost 40% were caused by infectious diseases and conditions such as pneumonia, diarrhoea, malaria, meningitis, tetanus, HIV and measles. Around 47% of all under-five deaths occurred in the neonatal period (within the first 28 days of life), the majority from preterm birth complications and intrapartum-related complications (complications during delivery). Globally, more than half of the under-five deaths are attributable to undernutrition (85).

Worldwide, the leading causes of death among children under-5 years include pneumonia (15.6% of all under-five deaths), preterm birth complications (17.9%), diarrhoea (8.2%), intrapartum-related complications (12%), malaria (5.1%), and neonatal sepsis (7.0%), meningitis (1.8%), tetanus (0.6%), measles (1.3%), injury (6.1%) and
others (14.3%). Cross-country comparisons show a wide variation among countries in the proportions of under-five deaths attributable to specific causes. Such variations indicate that optimal programmatic approaches for child survival will differ from country to country. Fig. 15 shows the causes of death of children under-five in 2016.

Summarizing data across regions and countries masks substantial differences in the distribution of causes of death. Approximately 90% of all malaria and HIV/AIDS deaths in children, more than 50% of measles deaths and about 40% of pneumonia and diarrhoeal deaths are in the African Region. On the other hand, deaths from injuries and non-communicable diseases other than congenital anomalies, account for 20-30% of under-five deaths in the region of the Americas and in the European and Western Pacific Regions (86).

The steady improvement in under-five survival is explained by a combination of advances. They include developments in science and technology (for example, oral rehydration salts that treat diarrhoeal dehydration and insecticide-treated mosquito nets for malaria prevention), improved health-seeking behaviours (such as women’s increasing use of antenatal care and skilled providers for care around the time of birth), improved sanitation and improved coverage of effective interventions to prevent or treat the most important causes of child mortality. Each one of these advances is due to the political will of committed governments and the expansion of innovative partnerships involving civil society and the public and private sectors. Taken together, these efforts are reducing the number of young lives claimed by the leading causes of under-five mortality: pneumonia, diarrhoea, malaria, measles and AIDS. As a result 3 million fewer children died from these five diseases in 2015 than in the year 2000 (86).

The Expanded Programme on Immunization started in 1974 and widened range of vaccines routinely provided, from smallpox, BCG and DPT to include polio and measles and more recently hepatitis B, Hbs, Rota virus vaccine and JE vaccine. It set-out to increase coverage in line with the international commitment to achieve the universal child immunization goal of 80 per cent coverage in every country.

As mortality from diarrhoeal diseases and vaccine preventable diseases decreased, pneumonia came to the forefront as a cause of death, and in the 1980s programmes were developed around simplified diagnostic and treatment techniques. In the meantime, promotion of breast-feeding continued, backed by international initiative and countries widely implemented the Baby-Friendly Hospitals initiative.

The Integrated Management of Childhood Illness (IMCI) strategy addresses the principal causes of child mortality i.e. diarrhoeal disease, acute respiratory infection, measles, malaria and underlying malnutrition. Several countries like India have added neonatal care in the national adaptations. It combines effective interventions for preventing death and for improving healthy growth and development, e.g., oral rehydration therapy for diarrhoea; antibiotics for sepsis, pneumonia and ear infection, antimalarials and insecticide-treated bed-nets; vitamin A, treatment of anaemia, promotion of breast-feeding and complementary feeding for healthy nutrition and for recovery from illness; and immunization. Some countries have included guidelines to treat children with HIV/AIDS, others for dengue fever, whooping cough, or for the follow-up of healthy children.

More recently, Every Newborn Action Plan proposes five strategic objectives for achieving two clear and measurable targets: (1) Ending preventable newborn deaths — By 2035, all countries reach a national target of 10 or fewer newborn deaths per 1000 live births and continue to close the gap in equity; and (2) Ending preventable stillbirths — By 2035, all countries reach the target of 10 or fewer stillbirths per 1000 total births and continue to narrow gaps in equity. Developed under WHO and UNICEF, the ENAP recommends the integrated delivery of high-impact interventions across the full continuum of maternal and newborn care, including care during labour, newborn care during the first week of life and care of small and sick newborns. Fig. 16 shows the package of interventions.

Child mortality rate in India

Each year about 27 million children are born in India. Around 10 per cent of them do not survive to 5 years of age. In absolute figures, India contributes to 25 per cent of the over 5.9 million under-five deaths occurring worldwide every year. Nearly half of the under-five deaths occur in neonatal period. The mortality rates for children below age 5 years for the year 2016, by residence are shown in Table 27.
UNDER-5 MORTALITY RATE

Focus of the Every Newborn Action Plan
The time around birth results in the majority of maternal and newborn deaths and stillbirths as well as human capital loss. These packages have the highest impact yet some of the lowest coverage of equitable and quality care across the continuum.

At the national level the mortality rate was estimated at 39 per 1000 live births, and the rate varies from 11 in Kerala to 55 in Madhya Pradesh. The rate for rural areas is about 43 and for urban areas 25. The mortality rate in female children in India is higher than the male children (81).

Among children who die before their fifth birthday, almost one-third die of infectious causes nearly all of which are preventable. The estimates of the cause of death for the year 2016 are shown in Fig. 17.

Preterm birth has emerged as the leading cause of death, accounting for 27.9% of all deaths before 5 years. Intrapartum-related complications, including birth asphyxia, account for 11.7% of deaths.

FIG. 16
Packages of interventions in the continuum of care

FIG. 17

Source: (85)
neonatal death, underlying the need for rapid scale-up of maternal health interventions in order to improve neonatal health outcomes.

Social determinants for maternal and child mortality include marriage and childbirth at a very young age, less spacing between births and low literacy level among women, in particular those belonging to the urban poor and rural settings, and socially-disadvantaged groups (such as scheduled caste and tribes). Access to and use of contraceptives, particularly modern, non-permanent contraceptives, and access to safe abortion services are also factors that influence maternal health and child survival. The TFR for those women who have no education is higher compared to those who are literate. Furthermore, there is a gradual decline of TFR with the increase in the level of education. Low level of education is itself linked to the low status of women, and associated risks such as violence against women, emotional and physical abuse and malnutrition (101).

A large number of maternal and child deaths are attributable to the 'three delays': (1) the delay in deciding to seek care, (2) the delay in reaching the appropriate health facility, and (3) the delay in receiving quality care once inside an institution. The delay in deciding to seek care can occur due to inadequate resources, poor access to high-quality health care and lack of awareness of the importance of maternal and newborn health care at the household level. The unavailability of basic reproductive health services, including contraceptives, pre and postnatal care and emergency obstetric and neonatal care, as well as delays in seeking institutional care and the poor quality of care provided in the health facility can potentially contribute to child deaths (101).

The reproductive, maternal, neonatal and child health packages that are currently being implemented under the NRHM address the most common causes of maternal and child deaths. However, the coverage of key interventions, such as antenatal care, deliveries by skilled birth attendants, and use of oral rehydration solution (ORS) for the management of childhood diarrhoea during the NRHM period has been slow and of variable quality across states.

To pursue the goals of NPP, the Government of India constituted a National Technical Committee on Child Health in June 2000. New initiatives taken on the basis of this are (63):

- Launch of Immunization Strengthening Project;
- Organization of RCH camps, health "melas" and RCH outreach scheme to reach disadvantageous segments of the population;
- Launch of Hepatitis B vaccine in the immunization programme;
- Operationalization of newborn care facilities in identified weak districts;
- Operations research by ICMR for provision of home-based neonatal care through community-level providers;
- Policy for exclusive breast-feeding up to 6 months of age;
- Preparation and approval of concept note on development of community-based midwives;
- Implementation of Dal training to provide key messages for newborn health in 166 districts; and
- Adaptation of IMCI to incorporate newborn issues and development of IMNCI.

The Government of India established an IMCI Adaptation Committee that has led the development of Integrated Management of Newborn and Childhood Illnesses (IMNCI). Separate tools and guidelines have been produced that focus on newborn issues; these are used to train field staff and for supervision and monitoring purposes.

In the year 2013, RMNCH+A strategy and in the year 2014, India Newborn Action Plan were launched in view to reduce the mortality rates in children. Newer vaccines were introduced in the national immunization schedule. Please refer to chapter 7 for details.

The Global Strategy for Women's, Children's and Adolescent's Health (2016–2030) and the 2030 agenda for Sustainable Development have three overarching objectives – Survive, Thrive and Transform. The SDGs contain ambitious targets for child mortality with SDG 3.2 seeking to end preventable deaths of newborns and children under 5 years. These include national targets of a USMR of no more than 25 per 1000 live births and neonatal mortality rate to no more than 12 per 1000 live births (57). Target 4.2, which calls for efforts to ensure that all girls and boys have access to quality early childhood development, care and pre-primary education; which is likely to have an impact on child mortality, while also improving children's chances of long and rewarding lives (57).

### CHILD SURVIVAL INDEX

The basic measure of infant and child survival is the Under-5 mortality (number of deaths under the age of 5 years, per 1000 live births). A child survival rate per 1000 births can be simply calculated by subtracting the Under-5 mortality rate from 1000. Dividing this figure by ten shows the percentage of those who survive to the age of 5 years (102).

\[
\text{Child survival rate} = \frac{1000 - \text{under-5 mortality rate}}{10}
\]

The following table (Table 30) shows the child survival rates of some countries.

The difference in the survival rates of children in developed and developing countries is a grim pointer to the Third World's need for preventive services. Through breast-feeding, adequate nutrition, clean water, immunization programmes, oral rehydration therapy and birth spacing, a virtual revolution in child survival could be achieved. The impact would be dramatic in humanitarian and fertility terms.
INTEGRATED MANAGEMENT OF CHILDHOOD ILLNESS (IMCI)

The notion of integration has a long history. Integration is supposed to tackle the need for complementarity of different independent services and administrative structures, so as to better achieve common goals. In 1950s, the goals were defined in terms of outcome, in 1960s of process and in the 1990s of economic impact. Integration has different meanings at different levels. At the patient level it means case management. At the point of delivery it means that multiple interventions are provided through one delivery channel, e.g., where vaccination is used as an opportunity to provide vitamin A to the child, boosting efficiency and coverage. At the system level integration means bringing together management and support function of different sub-programmes and ensuring complimentarity between different levels of care. IMCI is now the only child health strategy that aims for improved integration at these three levels simultaneously. More than just adding more programmes to a single delivery channel, it has sought to transform the way the health system looks at the child care.

Most sick children present with signs and symptoms related to more than one condition. This overlap means that a single diagnosis may not be possible or appropriate, and that treatment may be complicated by the need to combine therapy for several conditions. Surveys of the management of sick children at these facilities reveal that many children are not properly assessed and treated and that their parents are poorly advised. Providing quality care to sick children in these conditions is a serious challenge. In response to these challenge, WHO and UNICEF developed a strategy known as IMCI. The strategy combines improved management of childhood illness with aspects of nutrition, immunization, and other important disease prevention and health promotion elements. The objectives are to reduce deaths and the frequency and severity of illness and disability and to contribute to improved growth and development.

The strategy includes three main components:

1. Improvements in the case-management skills of health staff through the provision of locally adapted guidelines on IMCI and through activities to promote their use;
2. Improvements in the health system required for effective management of childhood illness; and
3. Improvements in family and community practices.

The core of the IMCI strategy is integrated case management of the most common childhood problems, with a focus on the most important causes of death i.e. diarrhoea, ARI, malaria, measles and malnutrition. A guided process of adaptation ensures that the guidelines, and the learning materials that go with them, reflect the epidemiology within a country and are tailored to fit the needs, resources and capacity of a country's health system.

The clinical guidelines, which are based on expert clinical opinion and research results, are designed for the management of sick children aged 1 week up to 5 years. They promote evidence-based assessment and management, using a syndromic approach that supports the rational, effective and affordable use of drugs. They include methods for assessing signs that indicate severe disease: assessing a child's nutrition, immunization, and feeding, teaching parents how to care for a child at home; counselling parents to solve feeding problems; and advising parents about when to return to a health facility. The guidelines also include recommendations for checking the parent's understanding of the advice given and for showing them how to administer the first dose of treatment.

When assessing a sick child, a combination of individual signs leads to one or more classifications, rather than to a diagnosis. IMCI classifications are action oriented and allow a health care provider to determine if a child should be urgently referred to another health facility, if the child can be treated at the first-level facility (e.g. with oral antibiotic, antimalarial, ORS, etc.) or if the child can be safely managed at home.

The complete IMCI case management process involves the following elements (103):

a. Assess a child by checking first for danger signs (or possible bacterial infection in a young infant), asking questions about common conditions, examining the child, and checking nutrition and immunization status. Assessment includes checking the child for other health problems.

b. Classify a child's illnesses using a colour-coded triage system. Because many children have more than one condition, each illness is classified according to whether it requires:
   - urgent pre-referral treatment and referral (pink), or
   - specific medical treatment and advice (yellow), or
   - simple advice on home management (green).

c. After classifying all conditions, identify specific treatments for the child. If a child requires urgent referral, give essential treatment before the patient is transferred. If a child needs treatment at home, develop an integrated treatment plan for the child and give the first dose of drugs in the clinic. If a child should be immunized, give immunization.

d. Provide practical treatment instructions, including teaching the caretaker how to give oral drugs, how to feed and give fluids during illness, and how to treat local infections at home. Ask the caretaker to return for follow-up on a specific date, and teach her how to recognize signs that indicate the child should return immediately to the health facility.

e. Assess feeding, including assessment of breast-feeding practices, and counsel to solve any feeding problems found. Then counsel the mother about her own health.

f. When a child is brought back to the clinic as requested, give follow-up care and, if necessary, reassess the child for new problems.

The IMCI guidelines address most, but not all, of the major reasons a sick child is brought to a clinic. A child returning with chronic problems or less common illnesses may require special care. The guidelines do not describe the management of trauma or other acute emergencies due to accidents or injuries.

Although AIDS is not addressed specifically, the case management guidelines address the most common reasons children with HIV seek care: diarrhoea and respiratory infections. When a child, who is believed to have HIV, presents with any of these common illnesses, he or she can be treated the same way as any child presenting with an illness. If a child's illness does not respond to the standard
treatments described or if a child becomes severely malnourished, or returns to the clinic repeatedly, the child is referred to a hospital for special care.

Case management can only be effective to the extent that families bring their sick children to a trained health worker for care in a timely way. If a family waits to bring a child to a clinic until the child is extremely sick, or takes the child to an untrained provider, the child is more likely to die from the illness. Therefore, teaching families when to seek care for a sick child is an important part of the case management process.

The case management process is presented on two different sets of charts: one for children age 2 months up to five years, and one for children age 1 week up to 2 months. Annexure A at the end of this chapter shows the flowchart about the IMNCI guidelines for the management of various conditions of childhood.

The Indian version of IMCI is known as IMNCI (Integrated Management of Neonatal and Childbirth Illness) as it includes the first 7 days of age in the programme. Please refer to page 497 chapter 7 for further details.

CONGENITAL MALFORMATIONS

Definitions

Congenital disorders are defined as "those diseases that are substantially determined before or during birth and which are in principle recognizable in early life." Some are obvious at birth like, cleft palate; some are obvious in early life like congenital dislocation of hip which may escape detection until walking should commence; and some may not become apparent until much later in life, like patent ductus arteriosus which may escape diagnosis until school age or even later. Internal defects, when they are not lethal, may go unrecognized. In addition to the list of late diagnoses are a host of inborn errors of metabolism like PKU, Tay-Sachs disease, galactosaemia, and mental retardation. Some defects are classified as major which may require surgical intervention, and some are classified as minor that have no functional implications like skin tags in front of the ear. Thus a broad definition of congenital malformation includes not only anatomical defects but also molecular and cellular abnormalities present at birth (104). A WHO document in 1972, however, held that the term congenital malformation should be confined to structural defects at birth, and the term congenital anomaly being used to include all biochemical, structural and functional disorders present at birth (87). Thus the basic difficulty in the study of congenital defects is the actual definition of the term without which comparisons between studies are difficult to make.

Incidence

Congenital anomalies (also referred as birth defects) affect approximately 1 in 33 infants and result in approximately 3.2 million birth defect-related disabilities every year. An estimated 270,000 newborns die during the first 28 days of life every year from congenital anomalies. Congenital anomalies may result in long-term disability, which may have significant impacts on individuals, families, health-care systems and societies. The most common serious congenital disorders are heart defects, neural tube defects and Down syndrome. Congenital anomalies may have a genetic, infectious or environmental origin; although in most of the cases it is difficult to identify their cause (105).

Causes

The aetiology of most congenital anomalies is poorly understood; both genetic and environmental factors have been implicated. They include:

1. GENETIC FACTORS: The congenital disorders with genetic aetiology are: (a) Chromosomal abnormalities: The chromosome is either missing or in excess. The examples include Down's syndrome, Klinefelter's syndrome and Turner's syndrome. (b) Inborn errors of metabolism: These include PKU, Tay-Sachs disease and galactosaemia. (c) Others: Other genetically inherited disorders, presumably due to single gene defects, are much more common than conditions with demonstrable chromosomal abnormalities. Single gene disorders may be dominant (e.g., Huntington's chorea), recessive (e.g., thalassaemia, sickle cell disease) or sex-linked disorders (e.g., haemophilia). (d) Those with probable or possible genetic aetiology: This applies to congenital dislocation of hip, club foot and neural tube defects.

2. ENVIRONMENTAL FACTORS: These include intrauterine infections (e.g., rubella, cytomegalovirus, toxoplasmosis, syphilis), Drugs (e.g., thalidomide, stilboestrol, anti-convulsants, tobacco, high dose of vitamin A during early pregnancy, alcohol, anaesthetics, etc.), Maternal diseases complicated by pregnancy (e.g., diabetes, cardiac failure), Irradiation, and Dietary factors (e.g., folic acid deficiency).

Incidence

It is now possible to detect certain congenital anomalies in utero using the following techniques: (a) Alpha fetoprotein: Neural tube defects can be detected by measurement of a specific protein of foetal origin, called alpha fetoprotein in maternal blood and in amniotic fluid during pregnancy. (b) Ultrasound: This can be used to visualize the foetus and detect many abnormalities of the foetus. (c) Amniocentesis: This test is possible only in the second trimester (i.e., after the completion of 12 weeks). It can detect many abnormalities (e.g., Down's syndrome, Neural tube defects). (d) Chorionic villi sampling: This new technique allows prenatal diagnosis at 9 to 11 weeks of pregnancy. By this test, the chromosome status can be easily determined. Prenatal diagnosis of congenital abnormalities offers the parents the option of therapeutic abortion.

PREVENTION OF CONGENITAL DEFORMITIES

There are 3 main approaches to the reduction of congenital abnormalities: (106). (1) By discouraging further reproduction after the birth of a malformed child; after such a birth, the frequency of malformations in subsequent pregnancies is increased by about 10 times; (2) The avoidance of pregnancy in circumstances where malformations are likely to occur, e.g., advanced maternal reproduction after the birth of a malformed child; after such a birth, the frequency of malformations in subsequent pregnancies is increased by about 10 times; (3) The avoidance of pregnancy in circumstances where malformations are likely to occur, e.g., advanced maternal age or even later. Internal defects, when they are not lethal, may go unrecognized. In addition to the list of late diagnoses are a host of inborn errors of metabolism like PKU, Tay-Sachs disease, galactosaemia, and mental retardation. Some defects are classified as major which may require surgical intervention, and some are classified as minor that have no functional implications like skin tags in front of the ear. Thus a broad definition of congenital malformation includes not only anatomical defects but also molecular and cellular abnormalities present at birth (104). A WHO document in 1972, however, held that the term congenital malformation should be confined to structural defects at birth, and the term congenital anomaly being used to include all biochemical, structural and functional disorders present at birth (87). Thus the basic difficulty in the study of congenital defects is the actual definition of the term without which comparisons between studies are difficult to make.

Incidence

Congenital anomalies (also referred as birth defects) affect approximately 1 in 33 infants and result in approximately 3.2 million birth defect-related disabilities every year. An estimated 270,000 newborns die during the first 28 days of life every year from congenital anomalies. Congenital anomalies may result in long-term disability, which may have significant impacts on individuals, families, health-care systems and societies. The most common serious congenital disorders are heart defects, neural tube defects and Down syndrome. Congenital anomalies may have a genetic, infectious or environmental origin; although in most of the cases it is difficult to identify their cause (105).
age and Down's syndrome; (3) the identification and removal of teratogens such as certain drugs (e.g., thalidomide, steroid hormones, folic acid antagonists, anti-convulsants); infective agents (e.g., rubella, cytomegalovirus, herpes simplex virus, varicella zoster virus, Toxoplasma gondii); and physical agents such as X-rays and irradiation, alcohol and pesticides. Immunization against rubella is now routine in many countries which is bound to lead to some reduction in congenital abnormalities. A largely untapped preventive measure is the avoidance of drugs in pregnancy except where they are absolutely necessary (107).

Congenital malformations may be regarded as one form of reproductive failure. The most unfavourable environmental and genetic factors result in sterility, and the favourable factors lead to normal reproduction. Between these extremes there may be abortions, stillbirths, premature births or neonatal deaths. Malformation represent a relative reproductive “success” when compared with sterility or early abortion (108). Penrose (1961) stressed that major advances in the prevention of malformations must be achieved by attention to environmental factors rather than by attempting to improve heredity. It is more within reach than genetic control (109).

SCHOOL HEALTH SERVICE

School health is an important branch of community health. According to modern concepts, school health service is an economical and powerful means of raising community health, and more important, in future generations. The school health service is a personal health service. It has developed during the past 70 years from the narrower concept of medical examination of children to the present-day broader concept of comprehensive care of the health and well-being of children throughout the school years.

Historical development

The beginning of School Health Service in India dates back to 1909, when for the first time medical examination of school children was carried out in Baroda city. The Bhore Committee (1946) (110) reported that School Health Services were practically non-existent in India, and where they existed, they were in an under-developed state. In 1953, the Secondary Education Committee emphasized the need for medical examination of pupils and school feeding programmes. In 1960, the Government of India constituted a School Health Committee to assess the standards of health and nutrition of school children and suggest ways and means to improve them. The Committee submitted its report in 1961, which contains many useful recommendations (111). During the Five Year Plans, many State Governments have provided for school health, and school feeding programmes. Inspite of these efforts to improve school health, it must be stated that in India, as in other developing countries, the school health services provided are hardly more than a token service because of shortage of resources and insufficient facilities.

HEALTH PROBLEMS OF THE SCHOOL CHILD

Any discussion of a school health service must be based on the local health problems of the school child, the culture of the community and the available resources in terms of money, material and manpower. While the health problems of school children vary from one place to another, surveys carried out in India indicate that the main emphasis will fall in the following categories: (1) malnutrition; (2) infectious diseases; (3) intestinal parasites; (4) diseases of skin, eye and ear; and (5) dental caries.

OBJECTIVES OF SCHOOL HEALTH SERVICE

The objectives of the programme of a school health service are as follows (112, 113):

1. The promotion of positive health;
2. The prevention of diseases;
3. Early diagnosis, treatment and follow-up of defects;
4. Awakening health consciousness in children; and
5. The provision of healthful environment.

Aspects of School Health Service

The tasks of a school health service are manifold, and vary according to local priorities. Where resources are plentiful, special school health services may be developed. Some aspects of a school health service are as follows:

1. Health appraisal of school children and school personnel.
2. Remedial measures and follow-up.
4. Healthful school environment.
5. Nutritional services.
7. Mental health.
8. Dental health.
11. Education of handicapped children.
12. Proper maintenance and use of school health records.

1. Health appraisal

The health appraisal should cover not only the students but also the teachers and other school personnel. Health appraisal consists of periodic medical examinations and observation of children by the class teacher. (a) Periodic Medical Examination: The school health committee (1961) in India recommended medical examination of children at the time of entry and thereafter every 4 years (111). In big cities, where facilities for medical examination are available, this could be more frequent. The initial examination should be thorough and unhastened and should include a careful history, physical examination, examination of faeces for intestinal parasites and urine should be carried out. Clinical examination for nutritional deficiencies and examination of faeces for intestinal parasitosis are particularly important in India. Tuberculin testing or mass screening should not be withheld. The parents should be persuaded to be present at these examinations. The teacher should help in the medical inspection by recording the medical history, regular (quarterly) recording of height and weight, annual testing of vision, preparing children for the medical examination by helping them understand the “how” and “why” of health appraisal. (b) School Personnel: Medical examination should be given to teachers and other school personnel as they form part of the environment to which the child is exposed. (c) Daily Morning Inspection: The teacher is in a unique position to carry out the “daily inspection”, as he is familiar with the children and can detect changes in the child’s appearance or behaviour that suggest illness or
improper growth and development. The following clues will help the school teacher in suspecting children who need medical attention: (1) unusually flushed face (2) any rash or spots (3) symptoms of acute cold (4) coughing and sneezing (5) sore throat (6) rigid neck (7) nausea and vomiting (8) red or watery eyes (9) headache (10) chills or fever (11) listlessness or sleepiness (12) disclination to play (13) diarrhea (14) pains in the body (15) skin conditions like scabies and ringworm (16) pediculosis (114). Children showing any such signs or symptoms should be referred to the school medical officer. Teacher observation of school children is of particular importance in India because of the limited number of trained personnel for school health work. For this work, the teachers should be adequately trained during Teacher Training Courses and subsequently by short In-service Training Courses.

2. Remedial measures and follow-up

Medical examinations are not an end in themselves; they should be followed by appropriate treatment and follow-up. Special clinics should be conducted exclusively for school children at the primary health centres in the rural areas, and in one of the selected schools or dispensaries for a group of about 5,000 children in the urban areas (113). The clinic days and time should be intimated to all the concerned schools. Considering the high prevalence of dental, eye, ear, nose and throat defects in the school children in India, special clinics should be secured or provided for the exclusive use of school children for examination and treatment of such defects. In the big cities, the required number of specialists should be employed in the School Health Service. There should be provision for beds in the existing referral hospitals for the children to be admitted for investigation and treatment as and when required.

3. Prevention of communicable diseases

Communicable diseases control through immunization is the most emphasized school health service function. A well planned immunization programme should be drawn up against the common communicable diseases

A record of all immunizations should be maintained as part of the school health records. When the child leaves school, the health record should accompany him.

4. Healthful school environment

The school building, site and equipment are part of the environment in which the child grows and develops. A healthful school environment therefore is necessary for the best emotional, social and personal health of the pupils. Schools should also serve as demonstration centres of good sanitation to the community. The following minimum standards for sanitation of the school and its environs have been suggested in India (112, 113, 115)

(1) Location : The school should normally be centrally situated with proper approach roads and at a fair distance from busy places and roads, cinema houses, factories, railway tracks and market places. The school premises should be properly fenced and kept free from all hazards

(2) Site : The site should be on a suitable high land, and not subject to inundation or dampness and can be properly drained. The School Health Committee (1961) had recommended that 10 acres of land be provided for higher elementary schools and 5 acres for primary schools with an additional one acre of land per 100 students. In congested areas, the nearest public park or playground should be made available to the students. (3) Structure : Nursery and secondary schools, as far as possible, be single storied. Exterior walls should have a minimum thickness of 10 inches and should be heat resistant. (4) Classroom : Verandas should be attached to classrooms. No classroom should accommodate more than 40 students. Per capita space for students in a classroom should not be less than 10 sq. ft. (5) Furniture : Furniture should suit the age group of students. It is desirable to provide single desks and chairs. Desks should be of "minus" type. Chairs should be provided with proper back-rests, with facilities for desk-work.

(6) Doors and windows : The windows should be broad with the bottom silt, at a height of 2'-6" from the floor level; combined door and window area should be at least 25 per cent of the floor space; windows should be placed on different walls for cross-ventilation; the ventilators should not be less than 2 per cent of the floor area. (7) Colour : Inside colour of the classroom should be white and should be periodically white-washed. (8) Lighting : Classrooms should have sufficient natural light, preferably from the left, and should not be from the front. (9) Water supply : There should be an independent source of safe and potable water supply, which should be continuous, and distributed from the taps. (10) Eating facilities : Vendors other than those approved by the school authorities should not be allowed inside school premises; there should be a separate room provided for mid-day meals. (11) Latrines : Privies and urinals should be provided — one urinal for 60 students and one latrine for 100 students. Arrangements should be separately made for boys and girls

5. Nutritional services

A child who is physically weak will be mentally weak, and cannot be expected to take full advantage of schooling. The diet of the school child should, therefore receive first attention. The diet should contain all the nutrients in proper proportion, adequate for the maintenance of optimum health. Studies in India have shown that nutritional disorders are widely prevalent among school children, particularly deficiencies relating to proteins; vitamins A, C, thiamine and riboflavin, calcium and iron.

Mid-day School Meal : In order to combat malnutrition and improve the health of school children, it is now an accepted procedure in all advanced countries to provide a good nourishing meal to school children. The School Health Committee (1961) recommended that school children should be assured of at least one nourishing meal (116). Those who can afford it may bring their lunch packets from home, and during lunch hours take their meals in school. Otherwise, schools should have some arrangement for providing mid-day meals through their own cafeteria on a 'no profit no loss' basis. In view of the limited finances in India, it is recommended that the school meal should provide at least one-third of the daily calorie requirement and about half of daily protein requirement of the child.

Applied Nutrition Programme : UNICEF is assisting in the implementation of the Applied Nutrition Programme in the form of implements, seeds, manure and water supply equipment. Wherever land is available, the facilities provided by the UNICEF should be utilized in developing school gardens. The produce may be utilized in the school feeding programmes as well as for nutrition education.

Specific Nutrients : Advances in the knowledge of nutrition have revealed that specific nutrients may be necessary for the prevention of some nutrient disorders
Dental caries, endemic goitre, nightblindness, protein malnutrition, anaemias and a host of other nutrient disorders are eminently preventable. Use of specific nutrients is indicated where such nutrient disorders are problems in a community.

6. First-aid and emergency care

The responsibility of giving first-aid and emergency care to pupils who become sick or injured on school premises rests with the teacher and therefore all teachers should receive adequate training during “Teacher Training Programmes” or “In-service Training programmes” to prepare them to carry out this obligation. The emergencies commonly met within schools are—(a) accidents leading to minor or serious injuries, and (b) medical emergencies such as gastroenteritis, colic, epileptic fits, fainting, etc. In every school a fully equipped First-Aid-Post should be provided as per regulations of St. John Ambulance Association of India.

7. Mental health

The mental health of the child affects his physical health and the learning process. Juvenile delinquency, maladjustment and drug addiction are becoming problems among school children. The school is the most strategic place for shaping the child’s behaviour and promoting mental health. The school teacher has both a positive and preventive role—he should be concerned with helping all children attain mental health, so that they may develop into mature, responsible and well adjusted adults. The school routine should be so planned that there is enough relaxation between periods of intense work, and every effort should be made to relieve the tedium of the class room. No distinction should be made between race, religion, caste or community: between the rich and poor; and between the clever and the dull. It is now increasingly realized that there is a great need for vocational counsellors and psychologists in schools for guiding the children into careers for which they are suited.

8. Dental health

Children frequently suffer from dental diseases and defects. Dental caries and periodontal disease are the two common dental diseases in India. A school health programme should have provision for dental examination, at least once a year. In the developed countries, dental hygienists are employed in schools to assist the school dentist with the examination of the teeth. They make preliminary inspection of the teeth and do prophylactic cleansing which is of great value in preventing gum troubles and in improving personal appearance. They take part in the teaching of dental hygiene as they work with the children.

9. Eye health services

Schools should be responsible for the early detection of refractive errors, treatment of squint and amblyopia, and detection and treatment of eye infections such as trachoma. Administration of vitamin A to children at risk, has shown gratifying results. In other words, basic eye health services should be provided in schools.

10. Health education

The most important element of the school health programme is health education. The goal of health education should be to bring about desirable changes in health knowledge, in attitudes and in practice, and not merely to teach the children a set of rules of hygiene.

Health education in schools should cover the following areas: (1) Personal hygiene: Health education programme in schools should be lively, practical and based on everyday needs and interests of children. The need for hygiene of skin, hair, teeth and clothing should be impressed upon them. Attention to posture is also important. Children often adopt bad postures while sitting and standing. Such tendencies, should be observed and corrected. It is increasingly recognized that the major degenerative diseases of adults have their origin in poor health habits formed early in life. Cigarette smoking is an example of a public health problem that should be tackled in schools. (2) Environmental Health: Encouraging young people to take part in health activities and keep their environment clean is an important function of school health services. (3) Family life: Family life education is being increasingly recognized as a priority in both developed and developing countries. The school health service is concerned not only with the development of healthy lives but also with healthy attitudes towards human reproduction.

Health education in schools is a function of the school teacher. The health officer and the public health nurse/health worker/health assistant may furnish teaching materials and advice, but the teacher is the key person in the presentation of the material to the children. To do this important work, the teacher should be well versed in health education techniques, and sincerely interested in the welfare of the pupils. Children take back to their parents the health instructions they receive in schools, and even more important, when they become adults they apply this knowledge to their own families. In developing countries, where ill-health is a major problem, “every school child is a health worker”.

11. Education of handicapped children

The ultimate goal is to assist the handicapped child and his family so that the child will be able to reach his maximum potential, to lead as normal a life as possible, to become as independent as possible, and to become a productive and self-supporting member of society. The resources for managing handicapped child vary from country to country. It requires the cooperation of health, welfare, social and educational agencies.

12. School health records

A cumulative health record of each student should be maintained. Such records should contain (a) Identifying data - name, date of birth, parent’s name and address, etc. (b) past health history (c) record of findings of physical examination and screening tests and record of services provided. The purpose of maintaining school health records is to have cumulative information on the health aspects of school children in order to give continuing intelligent health supervision. These records will also be useful in analysing and evaluating school health programmes and providing a useful link between the home, school and the community.

School health administration

The health of the school child is the responsibility of the parents, teachers, health administrators and the community.
The success or efficiency of school health service depends largely on effective coordination between the participating agencies. There is no uniform pattern of school health administration, both here and abroad. In England, school health service is part of the Education service of the country. In India, school health service is administered by different departments in different States – these are usually the departments of Health and Education. The School Health Committee set up by the Government of India in 1960 recommended that school health service should be an integral part of the general health services. The general health services in India are administered largely through the primary health centres in the rural areas, where the bulk of India's population lives. School health service is therefore an important function of the primary health centres.

(a) Primary health centres

The primary health centres are charged with the responsibility of administering school health service within their jurisdiction. It requires a whole-time, medical officer to cover 5,000 to 6,000 children a year. The School Health Committee (1961) has therefore recommended that the staff of the primary health centres should be augmented by additional staff to carry out effectively the school health programme.

(b) School Health Committees

The School Health Committee (1961) in India recommended the formation of school health committees at the village level, block level, district level, state level and national level. These Committees should mobilize community resources and make the school health programme continuous and self-supporting. The National School Health Council will be an advisory and coordinating body.

HANDICAPPED CHILDREN

Definitions

"Handicap" may be defined as "reduction in a person's capacity to fulfil a social role as a consequence of an impairment, inadequate training for the role, or other circumstances. Applied to children, the term usually refers to the presence of an impairment or other circumstances that are likely to interfere with normal growth and development or with the capacity to learn" (117).

International Classification of Impairments, Disabilities and Handicaps (ICIDH) : First published by WHO in 1980, this is an attempt to produce a systematic taxonomy of the consequences of injury and disease. In the year 2001, International Classification of Functioning, Disability and Health (ICF, WHO 2001) was published.

An impairment is defined as "any loss or abnormality of psychological, physiological, or anatomical structure or function". Impairments are disturbances at the level of the organ and include defects, loss of limb, organ or other body structure and defects or loss of mental function.

A disability is defined as "any restriction or lack (resulting from an Impairment) of ability to perform an activity in a manner or within the range considered normal for a human being". The term disability reflects the consequences of impairment in terms of functional performance and activity by the individual; disability thus represents disturbances at the level of the person.

A handicap is defined as a disadvantage for a given individual, resulting from an impairment or a disability, that limits or prevents the fulfillment of a role that is normal (depending on age, sex, and social and cultural practice) for that individual. The term handicap thus reflects interaction with and adaptation to the individual's surroundings.

Handicap may be intrinsic or extrinsic. For example, blindness is an intrinsic handicap, and loss of parents is an extrinsic handicap. One handicap can give rise to further handicaps and the terms "primary" and "secondary" are used to denote this relationship. Blindness is a primary handicap; it can lead to poverty, which will be secondary handicap.

Extent of the problem

Nearly 83 million of the world's population are estimated to be mentally retarded, with 41 million having long-term or permanent disability. It ranks fourth in the list of leading causes of disability. Hearing loss (41 decibels and above) over the age of 3 is estimated to affect 42 million people, ranking 3rd in the list. Disability resulting from poliomyelitis has affected about 10 million people (42). It is difficult to state how many people are mentally retarded in India as the census estimates do not cover mental handicap. About 16.15 million persons (1.9 per cent of the population) suffer from some or the other physical disability in the country. About 3 per cent child population in 1-14 years age group is affected by developmental delays (118).

Classification

It is usual to classify handicapped children into the following groups:

1. Physically handicapped
2. Mentally handicapped

1. Physically handicapped children

This category includes children who are blind, deaf and mute; those with hare-lip, cleft palate, talipes; and the "crippled" — e.g., resulting from polio, cerebral palsy, congenital heart disease, road accidents, burns, injuries, etc. These conditions fall into three broad causative groups:

(a) birth defects
(b) infections, and
(c) accidents. These are all preventable to a large extent through adequate prenatal, natal, postnatal services, and genetic counselling.

2. Mentally handicapped children

Mental handicap is the present term used for mental retardation. It is a condition of sub-average intellectual function combined with deficits in adaptive behaviour. Terms which were previously used such as idiot, moron and imbecile are now discarded. At least 2 per cent of India's population is said to be suffering from some kind of mental disability (119).

Causes

Mental handicap has many causes. These may be genetic, or environmental and include prenatal as well as postnatal causes. The possible and earliest time to recognize the problem of mental retardation is to look for any delayed milestones and development.

The known causative factors include the following:

(a) Genetic conditions: Down's syndrome, Klinefelter syndrome, PKU, Tay-Sach disease, galactosaemia.
microcephaly, congenital hypothyroidism involving both single and multiple gene action and chromosomal abnormalities. (b) Antenatal factors: These comprise neural tube defects, Rh incompatibility, certain infections (e.g., rubella, cytomegalovirus, toxoplasmosis, syphilis), drugs and irradiation. (c) Perinatal factors: These include birth injuries, hypoxia and cerebral palsy. (d) Postnatal factors: Head injuries, accidents, encephalitis, physical and chemical agents such as lead and mercury poisoning may result in mental retardation. (e) Miscellaneous: Maternal malnutrition, protein-energy malnutrition, iodine deficiency (endemic goitre), consanguineous marriages, pregnancy after the age of 40 (late marriages) are all known to be associated with mental retardation.

Categories of mental retardation

Psychologists have used the concept of IQ to classify the degree of mental retardation. The IQ scores rest on the assumption that intelligence distribution in the general public follow the normal or Gaussian curve, with a mean of 100. The half of the general population achieve scores above 100, and one half below. The lower 3 per cent or so of the population achieve scores of 70 or less. They are usually considered to be mentally retarded. The WHO gave the following classification of mental retardation:

- Mild mental retardation: IQ 50–70
- Moderate mental retardation: IQ 35–49
- Severe mental retardation: IQ 20–34
- Profound mental retardation: IQ under 20

Children scoring above 70 are no longer described as mentally handicapped. The number of mild cases far exceed the severe and profound cases. English statistics which have been widely quoted suggest that, among 100 mentally handicapped persons, the following proportion will be found: 70 mild, 20 moderate and 5 severe cases. In other words, a very great majority of cases of mental handicap are of the mild type and potentially capable of being taught to make a fairly adequate social adaptation in appropriate circumstances.

Severe mental retardation is uncommon. The great majority of severely handicapped children remain more or less dependent throughout life. Mental retardation often involves psychiatric disturbances. It has been stressed that the IQ range suggested must not be applied too rigidly. IQ level is not necessarily constant during the individual's life span.

3. Socially handicapped children

A "socially handicapped child" may be defined as a child whose opportunities for a healthy personality development and a full unfolding of potentials are hampered by certain elements in his social environment such as parental inadequacy, environmental deprivation (i.e. lack of stimulation of learning process), and emotional disturbances. Such children would include children who are orphaned either due to death or loss of parents; neglected and destitute children; those who are exploited or victimized; and, delinquent children. It may be pointed out that a child who is physically or mentally handicapped also meets with social handicaps to the extent to which he is subject to social rejection or misunderstanding and cannot make use of the normal value of social fulfilment.

More recently, WHO has come out with International classification of functioning disability and health (IFC).

International Classification of Functioning, Disability and Health (ICF)

Like ICD-10, ICF is a core classification in the WHO-FIC, where ICD-10 provides users an aetiologic framework for classification of disease, disorder and other health conditions, ICF classifies functioning and disability associated with health conditions. ICD-10 and ICF are complementary classifications and WHO encourages users to use both systems together to create a broader and more meaningful picture of health of individuals and populations.

Developed by WHO, ICF represents a revision of the International Classification of Impairment, Disability and Handicaps (ICIDH). The focus of ICIDH was consequences of disease whereas focus of ICF is "components of health". ICF is a classification of health and health related domain that describe body function and structure, activities and participation. Since an individual's functioning and disability occur in a context, ICF is a tool for measuring functioning in society, no matter what the reason for one's impairment.

The model of ICF

Two major model of disability have been proposed. The medical model views disability as a feature of the person, directly caused by disease, trauma or other health conditions; which requires medical care provided in the form of individual treatment by professionals. The social model of disability, on the other hand, sees disability as a socially-created problem and not at all an attribute of an individual. On the social model, disability demands a political response, since the problem created by an unaccomodating physical environment brought about by attitude and other features of the social environment.

Components of ICF

The ICF framework consists of two parts:

a. Functioning and disability
b. Contextual factors

a. Functioning and disability includes:

- Body function and structure - describes actual anatomy and physiology of human body.
- Activity and participation - describes the person's functional status, including communication, mobility, interpersonal interactions, self-care, learning, applying knowledge, etc.

b. Contextual factors includes:

- Environmental factors - factors that are not within the person's control, such as family, work, government agencies, laws, and cultural beliefs.
- Personal factors - include race, gender, age, educational level, coping styles, etc.

ICF is used by persons with disability and professionals alike to evaluate health care settings that deal with chronic illness and disability, such as rehabilitation centres, nursing homes, psychiatry institutions and common services.
The broad objective for all children whatever their condition or problem is to bring them as close to normality as possible — physically, mentally and socially. This will involve: (a) Early diagnosis of handicap: Parents themselves have the responsibility to bring the child to paediatrician and seek advice. Investigation of the child requires full history, assessment of the degree of handicap and perhaps special investigations including the natural potentialities of the child. This should be done through MCH and School Health Services and such other agencies. (b) Treatment: Handicapped children need specialized treatment facilities such as physiotherapy, (the deformities are corrected, the weakened muscles are given exercise as in polio, infrared rays, diathermy etc.); occupational therapy (the child is taught, according to his ability and taste, things like music, painting, weaving, woodwork, pottery, basket making etc.); speech therapy (the child is trained to talk normally); and prosthetics (provision of artificial limbs, hearing aids and other equipment). The modern term for this branch of medicine is “Physical Medicine and Rehabilitation”. The purpose of treatment is to improve the physical condition of the patient. (c) Training and education: the handicapped child is trained for an independent living. This is called “vocational guidance”. He is trained to “work with what is left”, so that he is not a burden on others. In India, there are over 150 schools and institutions for the handicapped. The following are some of the important ones: (1) Occupational Therapy School, Mumbai; (2) Physical Therapy School, Mumbai; (3) Occupational Therapy School, Nagpur; (4) All India Institute of Physical Medicine and Rehabilitation, Mumbai; (5) Institute of Physical Medicine and Rehabilitation, Christian Medical College, Vellore; and (6) Occupational Therapy College, New Delhi. Beside these, there are schools for the blind, deaf, and special hospitals and wards for crippled children. Institutional care of the handicapped children is being replaced by various social support measures and services, enabling families to assume a larger share of rehabilitation within the family cycle (35).

The mentally handicapped children can be helped to reach their optimal capacity through attention to the following: (a) they should get love and warmth, patience and tolerance, besides discipline (b) their natural potentials should be identified, and the child must be helped to develop in that direction in all possible manner.

The mentally handicapped require attention from diverse disciplines such as medicine, psychology, education, rehabilitation and social welfare. Taking into account the gravity of the problem, the Ministry of Social Welfare, Govt. of India, has set-up the National Institute for Mentally Handicapped (NIMH) in 1984 at Secunderabad. It has Regional Branches at Mumbai, New Delhi and Kolkata. The NIMH serves as an apex organization for developing appropriate models for care for the mentally handicapped (119).

Apart from NIMH, 3 other premier National Institutes are working in specific disabilities: (a) Ali Yavar Jung National Institute for the Hearing Handicapped, Mumbai with Regional branches at New Delhi, Kolkata and Secunderabad; (b) National Institute for the Visually Handicapped, Dehradun with Regional branch at Chennai; (c) National Institute for the Orthopaedically Handicapped, Kolkata. Apart from developing models for care and services, these institutions conduct research, promote human resource development, crises management, education, placement and employment, development and supply of appropriate aids and appliances, and documentation and dissemination of information (118).

In India, the Ministry of Social Welfare operates through five major schemes of assistance to voluntary organizations.
providing services to disabled persons. These are:
(a) Assistance to voluntary organizations for the disabled:
Assistance up to 90% per cent in urban and 95% per cent in rural
areas is given to NGOs for education, training and
rehabilitation of the disabled; for rehabilitation of people
recovering from mental illness; emphasis on vocational
guidance and training; liaison with nearest psychiatrist centre
or hospital; provision for Half-way Homes. (b) Assistance for
aids and appliances: Aids and appliances up to Rs 3,600 are
provided to people with disabilities free, if the monthly income
is up to Rs 1,200, and at 50 per cent cost if the monthly income
is between Rs 1,201 to 2,500. (c) Assistance to voluntary
organizations for rehabilitation of leprosy-cured persons:
Assistance to voluntary organizations working for leprosy-
cured persons is given up to 90 per cent for public education
and awareness, early intervention, educational and vocational
training, economic rehabilitation and social integration.
(d) Development in the field of cerebral palsy and mental
retardation: For manpower training of professionals and also
for developing organizational infrastructure such as class
rooms/library/hostel in the field of cerebral palsy and mental
retardation. (e) Assistance to voluntary organization for
establishment of special schools; For setting up special schools
NGOs receive grants up to 90 per cent. Preference is given for
opening schools in new districts and upgradation of existing
schools.

of India introduced a comprehensive Bill in the Parliament
known as “Persons with disabilities (equal opportunities,
protection of rights and full participation) Bill 1995”. It
Deals with preventive and promotional aspects of
rehabilitation.

The Rights of Persons with
Disabilities Bill - 2016

The Lok Sabha has passed “The Rights of Persons with
Disabilities Bill-2016”. The Bill will replace the existing PwD
Act, 1995, which was enacted 21 years back. The Rajya
Sabha has already passed the Bill on 14.12.2016. The
salient features of the Bill are (123):

Disability has been defined based on an evolving and
dynamic concept. The types of disabilities have been
increased from existing 7 to 21 and the Central Government
will have the power to add more types of disabilities. The 21
disabilities are given below:
1. Blindness
2. Low vision
3. Leprosy cured persons
4. Hearing impairment (deaf and hard of hearing)
5. Locomotor disability
6. Dwarfism
7. Intellectual disability
8. Mental illness
9. Autism spectrum disorder
10. Cerebral palsy
11. Muscular dystrophy
12. Chronic neurological conditions
13. Specific learning disabilities
14. Multiple sclerosis
15. Speech and language disability
16. Thalassemia
17. Hemophilia
18. Sickle cell disease
19. Multiple disabilities including deaf blindness
20. Acid attack victim
21. Parkinson’s disease

Speech and language disability and specific learning
disability have been added for the first time. Acit attack
victims have been included. Dwarfism, muscular dystrophy
have been indicated as separate class of specified
disability. The new categories of disabilities also include three
blood disorders, thalassemia, hemophilia and sickle cell
disease. In addition, the government has been authorized to
notify any other category of specified disability.
Responsibility has been cast upon the appropriate
government to take effective measures to ensure that the
persons with disabilities enjoy their rights equally as others.

In considering the management of the socially
handicapped child, we must remember that such children
are normal in their needs and development. Their needs
should be identified and met. The children Act, 1960
provides for the “care, protection, maintenance, welfare,
training, education and rehabilitation” of the socially
handicapped children.

Lastly, we need to strengthen the family. The family is the
most effective bulwark to prevent children from becoming
socially handicapped. There were times when the
handicapped child was considered a liability to the parents
and to the society. All over the world, there is an awakening
that handicapped children can and must be helped to make
their lives as happy and useful as possible.

BEHAVIOUR PROBLEMS

The behaviour problems in children may be classified as
below:
(a) Problems antisocial in nature: Stealing, lying,
gambling, cruelty, sexual offences, destructiveness.
(b) Habit disorders: Thumb sucking, nail-biting, bed-
wetting, masturbation.
(c) Personality disorders: Jealousy, temper-tantrums,
imidity, shyness, day-dreaming, fears and anxieties,
unsociability, hysterical manifestations.
(d) Psychosomatic complaints: Tremors, headache,
asthma, depression, delusion, hallucinations.
(e) Educational difficulties: Backwardness in studies,
school phobia, school failures, etc.

Some of the behaviour disorders are due to mental
deficiency; some are due to organic disease and some due to
failure in adjustment to external environment. The answer to
these problems lies in improvement of living conditions,
better social environment and education.

JUVENILE DELINQUENCY

The Children Act, 1960 in India defines delinquent as
“a child who has committed an offence”. Juvenile means a
boy who has not attained the age of 16 years and a girl who
has not attained the age of 18 years. In a broad sense,
delinquency is not merely “juvenile crime”. It embraces all
deviations from normal youthful behaviour and includes the
incorrigible, ungovernable, habitually disobedient and those
who desert their homes and mix with immoral people, those
with behaviour problems and indulge in antisocial practices.
INCIDENCE: In the United States it is reported that 2 per cent of children between 7 and 17 years attend juvenile courts. Comparable statistics are not available in India to denote the size of the problem, but it is agreed that juvenile delinquency is on the increase in India during the past few decades, due to changes in the cultural pattern of the people, urbanization and industrialization. The highest incidence is found in children aged 15 and above. The incidence among boys is 4 to 5 times more than among girls.

CAUSES: (1) Biological causes: Certain biological causes such as hereditary defects, feeble-mindedness, physical defects and glandular imbalance may be at the bottom of juvenile delinquency. Recent studies indicate that chromosome anomaly might be associated with a tendency for delinquency and crime. A survey of criminal patients in Scotland and elsewhere demonstrated such a link — some of the patients showing an extra Y chromosome. The XYY men suffer from severe disturbance of the whole personality (122). (2) Social causes: Among the social causes may be mentioned broken homes, e.g., death of parents, separation of parents, step mothers and disturbed home conditions, e.g., poverty, alcoholism, parental neglect, ignorance about child care, too many children, etc. (3) Other causes: Absence of recreation facilities, cheap recreation, sex—thrillers, urbanization and industrialization, cinemas and television, slum-dwelling, etc.

PREVENTIVE MEASURES: (1) Improvement of family life: A well adjusted family can stem the tide of delinquency. Parents should be prepared for parenthood. The needs of children should be appreciated and met. (2) Schooling: The school comes next to home in the community in ordering the behaviour of children. There should be a healthy teacher—pupil relationship. The school teacher can play an important part by detecting early signs of maladjustment. (3) Social welfare services: These comprise recreation facilities, parent—counselling, child guidance, educational facilities and adequate general health services.

Children in difficult circumstances (65)

In a globalized economy, the increased vulnerability of some children due to their identity, and/or their socio-economic and geo-political circumstances calls for more focused attention as well as coordination of social and economic policies and monitoring of child impact. Besides being victims of globalization, these children may be barred from benefits meant for all children simply because they belong to a group or community with difficulties of access. These barriers must be overcome.

Over the years, some children have been categorized as children in difficult circumstances and these categorizations include:

- Homeless children (pavement dwellers, displaced/evicted, etc.).
- Orphaned or abandoned children.
- Children whose parents cannot or are not able to take care of them.
- Children separated from parents.
- Migrant and refugee children.
- Street children.
- Working children.
- Trafficked children.
- Children in prostitution.
- Children of sex workers/prostitutes/sexual minorities.
- Children of prisoners.
- Children affected by conflict.
- Children affected by natural disasters.
- Children affected by HIV/AIDS.
- Children suffering from terminal diseases.
- The girl child.
- Children with disabilities and related special needs.
- Children belonging to the ethnic and religious minorities, and other minority communities, and those belonging to the Scheduled Castes and Scheduled Tribes
- Children in institutional care, be it in state-run institutions or religious and other charitable institutions.
- Children in conflict with law (those who commit crimes).
- Children who are victims of crime.

For the first time in the history of planning for children, India has adopted a clear understanding and definition of the child in the NPAC 2005. The NPAC definition of the child as a person up to the age of 18 years and its clear declaration that “all rights apply to all age-groups, including before birth” reiterates the 1974 National Policy mandate that the State takes responsibility for children “both before and after birth,” and the child’s interests are to receive paramount attention. This national reaffirmation must set the frame for future planning and intervention to secure the well-being of all children of the country and provide them a caring and protective environment.

Battered baby syndrome

It has been defined as “a clinical condition in young children, usually under 3 years of age who have received non-accidental wholly inexcusable violence or injury, on one or more occasions, including minimal as well as severe fatal trauma, for what is often the most trivial provocation, by the hand of an adult in a position of trust, generally a parent, guardian or foster parent. In addition to physical injury, there may be deprivation of nutrition, care and affection in circumstances which indicate that such deprivation is not accidental”.

Battered baby syndrome has been found in all strata of society. Its incidence is not known. So far as sequelae are concerned, the most worrying is the risk of mental and neurological complications. Thus it has been tentatively suggested that 10–15 per cent of cases of cerebral palsy and almost double that proportion of the newly mentally retarded children each year may be the result of the battered baby syndrome.

Girl child and gender bias (65)

Gender biases pose a specific threat to girl children across the social and economic strata. For a girl child, life is a constant fight for survival, growth and development from the time she is conceived till she attains 18 years. The life chart of a girl child and the many life threatening problems she faces are as follows:
<table>
<thead>
<tr>
<th>Years</th>
<th>Problems faced</th>
</tr>
</thead>
</table>
| Before birth to 1 year | Being unwanted, risk of prenatal detection.  
|           | Foeticide and infanticide.  
|           | Infant mortality.  
|           | Discrimination in breast-feeding and infant food.  
|           | Neglect of health (immunization).  
| 1 to 5 years | Discrimination in access to food.  
|           | Poorer health attention and poorer access to health care; high risk of nutritional anaemia  
|           | Discrimination in overall treatment, parental care; expression of value and worth.  
|           | Vitamin and micro-nutrient deficiencies.  
|           | Early definition and imposition of ‘suitable’ roles; limits on permitted learning and play activities.  
|           | Child marriages in some areas of country.  
|           | Household/near-home sexual abuse.  
|           | If enrolled in school, less time for learning.  
|           | Assignment of domestic duties, minor small domestic chores.  
| 6 to 11 years | Malnutrition and anaemia.  
|           | Health problems like diarrhoea.  
|           | Iodine and Vitamin A deficiency.  
|           | Low school enrolment, school drop outs.  
|           | Vulnerable to trafficking, child labour, child marriage.  
|           | Abuse, exploitation and violence.  
|           | Increasing domestic duties/workload.  
|           | Looking after siblings.  
|           | Restrictions on mobility, play.  
| 12 to 18 years | Poor health, poor health attention.  
|           | High risk/high levels of anaemia.  
|           | Frequent illness due to malnutrition and micro-nutrient deficiency.  
|           | Child marriage.  
|           | High-risk/incidence of early child-bearing related morbidity/mortality.  
|           | Becoming a 'child-mother', health risks and burden of child-care.  
|           | Denied information, mobility, access to services.  
|           | Low literacy/learning level.  
|           | Early and frequent pregnancy coupled with abortions.  
|           | Maternal and domestic violence.  
|           | Dowry harassment, desertion, polygamy, divorce.  
|           | Child labour, trafficking.  
|           | STDs and HIV/AIDS.  
|           | Unpaid and unrecognized work, and drudgery.  
|           | No voice either in home or society.  

It is evident from the text above that age-specific and setting-specific interventions have to be put in place for appropriate and effective response to the above problems, highlighting the inter-sectoral nature of actions required.

Protecting girl children in India will not be easy. The nation cannot any longer afford the cost of hoping that society will change its mindset on its own, in a situation where pervasive negative attitudes towards women are being reflected on girl children, to the extent of denying them life itself.

The well-being of daughters in the community must become the subject of government monitoring (with NGO assistance if appropriate), covering every age and stage of childhood. Such vigilance should apply to all stages of a girl child's childhood. The specific goals for girls in the National Plan of Action for Children 2005

- Assurance of equality of status for girl child as an individual and a citizen in her own right through promotion of special opportunities for her growth and development.
- To ensure survival, development and protection of the girl child and to create an environment wherein she lives a life of dignity with full opportunity for choice and development.
- To stop sex selection, female foeticide and infanticide.
- To eliminate child marriages.
- To ensure the girl child's security and protect her from abuse, exploitation, victimization and all other forms of violence.
- To protect the girl child from deprivation and neglect and to ensure to the girl child an equal share of care and resources in the home and community, and equal access to services.
- To take measures to protect girl children from any treatment which undermines their self esteem, and causes their exclusion from social mainstream and also to break down persistent gender stereotype.
- To eliminate all obstacles that prevent girls from full enjoyment of human rights and fundamental freedom including equal rights in succession and inheritance.
- To ensure equal opportunity for free and compulsory elementary education to all girls.
- Health and nutrition.

**Child abuse**

The WHO defines child abuse and child maltreatment as "all forms of physical and/or emotional ill-treatment, sexual abuse, neglect or negligent treatment or commercial or other exploitation resulting in actual or potential harm to the child's health, survival, development or dignity in the context of a relationship of responsibility, trust or power". The Center for Disease Control and Prevention (CDC) uses the term child maltreatment to refer to both acts (abuse), or acts of omission (neglect) (124). These public health problems include all types of abuse and neglect (125).

a. Physical abuse – It is the intentional use of physical force that can result in physical harm. Examples include hitting, kicking, shaking, burning or other show of force against a child.

b. Sexual abuse – It involves pressuring or forcing a child to engage in a sexual act. It includes behaviours such as
The strategies and approaches to prevent child abuse can be summarized as:

a. Strengthen economic support to the family;
b. Change social norms to support parents and positive parenting;
c. Provide quality care and education early in life;
d. Enhance parenting skills to promote healthy child development;
e. Intervene to lessen harms and prevent future risk; and
f. Child protection.

Studies carried out throughout the past two decades have shown that the provision of supportive home visitors, either public health nurse or trained lay people, to families who are at risk of using violence against children can prevent the abuse from happening. However, we have not yet reached a similar level of confidence about our ability to prevent the sexual abuse of children, which is also a worldwide phenomenon.

**Street children**

The UN defines street children as "boys and girls for whom the street has become their home and/or source of livelihood and who are inadequately protected or supervised by responsible adults".

The issue of street children is considered to be an urban problem. There are three major categories of street children:

1. Children who live on street with their families and often work on street. They may be from migrated families or temporarily migrated and are likely to go back to their home;
2. Children who live on the street by themselves or in groups and have remote access or contacts with their families in the village; and
3. Children who have no ties to their families such as orphans, refugees or runaways.

According to UNICEF street children fall under two categories: "on the street" and "of the street". Children of the street are homeless who live and sleep on the streets in the urban areas. They are on their own and do not have parental supervision or care though some do live with other homeless adults. Children on the street earn a livelihood from street such as street urchins and beggars. They return home at night to have contact with their families. The distinction is important one because children of the street lack emotional and psychological support of a family.

A large number of children without any family support, particularly in the megacities of the developing world are at high-risk of malnutrition, tuberculosis, STDs including HIV, parasitic and worm infestation and skin diseases. Both sexes are highly vulnerable to drug abuse, prostitution and criminal exploitation.

Most street children describe major losses in their lives. Many have lost family members through diseases, natural or manmade disasters, or may be by-product of war and riots.

Although poverty and rapid urbanization are major contributing factors to the problem, many claim that physical and sexual abuse were the reason for their leaving home.

During the year 2003, global estimates placed their number at as many as 100 million. There may be 40 million in Latin America, 25 million in Asia and 10 million in Africa, with about 25 million in other areas including the developed world. In 1993 WHO launched an Innovative project to study links between street children and substance abuse. The study noted regular use of alcohol and other drugs by a major proportion of street children. Often the lives of street children are intimately entwined with the illicit drug industry. Street children are used in the production and marketing of cocaine and the trafficking of cannabis and heroin.

There are particular problems in the provision of health and welfare services to street children with regard not only to health care but also to housing, educational opportunities and employment. The rehabilitation of these children should be taken up by the government and non-government voluntary agencies.

The "Integrated Programme for Street Children" without homes and families was launched to prevent destitution of children and provide facilities for their withdrawal from life on the streets. During 2008-09 the scheme was merged to Integrated Child Protection Scheme. Under the scheme NGOs are given financial support to run 24 hour shelters and provide food, clothing, non-formal education,
recreation, counselling, guidance and referral services for children. The other components of the scheme include enrolment in schools, vocational training, occupational placement, mobilizing preventive health services and reducing incidence of drug substance abuse, HIV/AIDS etc. (66).

Refugee and displaced children (126)

At the end of 2004, roughly 48 per cent of all refugees worldwide were children.

During the same year, the total number of people displaced within their own countries by conflict or human rights violations amounted to roughly 25 million.

Refugee and internally displaced children face many risks, given the violence and uncertainty surrounding both their flight and their lives in the country and/or place of asylum. They may become separated from their families, lose their homes and find themselves living in poor conditions that jeopardize their health and education.

Displacement complicates birth registration and the issuance of travel documents, thereby compromising displaced persons' right to an identity. Both refugees and internally displaced people may have been forced to leave their homes without proper documentation, making it difficult to establish their identities. They may, therefore, be unable to prove their right to receive basic social services, such as education or health care, or to work in a different part of the country.

The loss of family protection, and inadequate resources to address the needs and challenges that refugee and internally displaced children face, can leave them at significant risk of recruitment by armed groups and forces, abuse and sexual exploitation. Girls are especially at risk of abduction, trafficking and sexual violence, including rape used as a weapon of war.

Orphaned children are much more vulnerable to protection violations. The death of a parent, in situations where no adequate alternative care systems are in place, opens up a protection gap. Children living on their own are at much greater risk of abuse and exploitation. Assessments by the International Labour Organization (ILO) have found that orphaned children are much more likely than non-orphans to be working in commercial agriculture, as street vendors, in domestic service and in the sex trade.

Primary responsibility for both refugee and displaced children lies with national governments. However, the Office of the United Nations High Commissioner for Refugees (UNHCR) has a mandate to assist and protect refugees, while the International Committee of the Red Cross (ICRC) has a mandate to assist internally displaced people if displacement is a result of armed conflict and internal violence.

Child labour and child exploitation

A sizeable number of growing children of poor socioeconomic class especially in rural areas are known to be inducted as child labour. Studies have shown that labour at very young ages can have dire consequences on the child's development, both physical and mental. Child labourers always had lower growth and health status compared to their non-working counterparts, besides exposure to occupational hazards at a very young stage in their lives. The Declaration of the Rights of the Child and our own Constitution has laid down that childhood and youth should be protected against exploitation. In 1973, the ILO passed a convention establishing 15 as the minimum work age for most sectors while permitting light work from age 13, provided that such work was unlikely to harm child's health, morals and safety or prejudice his school attendance (127).

The facts and figures of child labour are summarized as (128):

1. Worldwide 218 million children between 5 and 17 years are in employment. Among them, 152 million are victims of child labour, almost half of them, about 73 million work in hazardous conditions.
2. In absolute terms, almost half of child labour (72.1 million) is in Africa; 62.1 million in the Asia and the Pacific; 10.7 million in the Americas; 1.2 million in the Arab States and 5.5 million in Europe and Central Asia.
3. In terms of prevalence, 1 in 5 children in Africa (19.6%) are in child labour, whilst prevalence in other regions is between 3% and 7%; 2.9% in the Arab States (1 in 35 children); 4.1% in Europe and Central Asia (1 in 25); 5.3% in the Americas (1 in 19) and 7.4% in Asia and the Pacific region (1 in 14);
4. Almost half of all 152 million children victims of child labour are aged 5–11 years.
5. Hazardous child labour is most prevalent among the 15–17 years old. Nevertheless up to a fourth of all hazardous child labour (19 million) is done by children less than 12 years old.
6. Among 152 million children in child labour, about 88 million are boys and 64 million are girls.
7. 58% of all children in child labour and 62% of all children in hazardous work are boys. Boys appear to face a greater risk of child labour than girls, but this may also be a reflection of an under-reporting of girls' work, particularly in domestic child labour; and
8. Child labour is concentrated primarily in agriculture (71%), which includes fishing, forestry, livestock herding and aquaculture, and comprises both subsistence and commercial farming; 17% in service; and 12% in the industrial sector, including mining.

According to ILO, forced child labour is present in all regions and kinds of economy. For the most part, there is neither official data on the incidence of forced labour nor a widespread awareness among society at large that forced labour is a problem. Children in domestic service are the most invisible child labourers. Their work is performed within individual homes, removed from public scrutiny and their conditions of life and labour are entirely dependant on the whims of their employers. The number of children involved in domestic service around the world is unquantifiable because of the hidden nature of the work, but it certainly runs into millions. Many of these children are girls, and in many countries domestic service is seen as the only avenue of employment for a young girl, though in some places, such as Nepal and South Africa, boys are more likely to be domestic workers than girls. Children exploited in domestic service are generally paid little or nothing over and above food and lodging. In addition, children in domestic service are especially susceptible to physical and psychological harm. Many are forced to undertake tasks that are completely inappropriate for their age and physical strength. Another form of forced labour is debt bondage, whatever the origin of the debt, it leaves children under complete control of a money lender in a state little distinguishable from slavery.
India fosters the largest number of child labour in the world. In 2014, about 82.2 lakh child labour population was estimated in India. Child labour contributes about 20 per cent of India's GNP. Child workers work for 12 hours at an average every day (129). Jammu and Kashmir has the highest percentage of child labour, where children are mainly engaged in carpet weaving industry. The other fields where child labour is used is in agriculture, plantations, mining, building construction, beedi-making, garbage picking, cashew descaling and processing, cloth printing, dyeing and weaving etc.

In India, various items of health and social legislation have been enacted to protect the health, safety and welfare of working children below the age of 15 years

The Child Labour (Prohibition and Regulation) Act, 1986

Except in the process of family-based work or recognized school-based activities, children are not permitted to work in occupations concerned with:

- Passenger, goods mail transport by railways.
- Carpet weaving.
- Cinder picking, cleaning of ash-pits.
- Cement manufacturing.
- Building construction operations.
- Cloth printing.
- Dyeing, weaving.
- Manufacturing of matches, explosives, fire-works
- Beedi making
- Mica cutting, splitting.
- Abattoirs.
- Wool cleaning.
- Printing
- Cashew descaling and processing.
- Soldering process in electronic industries.

Child labour is rooted in poverty, unemployment and lack of education. A great deal of effort is needed to eliminate these basic causes. It is felt that instead of proliferating the laws relating to children, all the statutory provisions of the various Acts relating to children should be grouped in one comprehensive code of children. It is not feasible to abolish child labour entirely in the present context, but it is expedient to protect such children against abuse, exploitation and health hazards, and regulate the conditions of work in occupations where child labour is permitted.

Child Trafficking (126)

Child trafficking is the recruitment, transportation, transfer, harbouring or receipt of a child for the purpose of exploitation. A child trafficker is anyone who contributes to an element of the trafficking process with the intent to exploit the child. This includes those who play only a part in the entire process, such as recruiters, intermediaries, document providers, transporters, corrupt officials, service providers and unscrupulous employers. Girls are trafficked disproportionately for commercial sexual exploitation and child domestic labour. The ILO 2005 Global Report estimates that Asia has the highest number of child trafficking victims followed by industrialized countries, Latin America and Caribbean, the Middle East Countries (126 A).

"Poverty-plus" at source, transit and destination: Poverty alone does not guarantee that a child will be trafficked, usually it is poverty plus one or many other risk factors that make a child vulnerable to trafficking. These could be at the individual, household, community or institutional level. Some common causes of vulnerability include lack of birth registration, discrimination, orphanhood, illness in the family, family abuse, conflict or natural disaster, travelling alone or through a non-registered agency or smuggler, inability to speak the language, unregulated informal economy, weak legal framework and enforcement, corruption and a large youth population with low labour market absorption. Vulnerability is not static. It changes over time, and different risk factors are present in different contexts (126 A).

Trafficking of children takes many different forms. Some children are forcibly abducted, others are tricked and still others opt to let themselves be trafficked by promise of earnings, but not suspecting the level of exploitation they will suffer at the other end of the recruiting chain. Trafficking always involves journey, whether within the country or across the international border. The relocation takes children away from their families, communities and support net-work, leaving them isolated and utterly vulnerable to exploitation. Collecting data about these children is very difficult. It is estimated that trafficking affects about 1.2 million children each year.

Though the trafficking of children is a shadowy practice, some dominant regional patterns are identifiable. In West and Central Africa, children are "placed" in a marginal position within other families. This practice is being used to exploit children both within and outside home. Children are also trafficked into plantations and mines, and in those countries affected by conflict, they are directly abducted by militias. In East Asia and Pacific, most trafficking is into child prostitution, though some children are also recruited for industrial and agricultural work. In South Asia, trafficking forms most of immense child labour problem. In the sub-continent, often related to debt bondage. In addition, significant number of children are trafficked for other purposes, including into prostitution, carpet and garment factories, construction projects and begging. In Europe, children are mainly trafficked from east to west, reflecting the demand for cheap labour and child prostitution in richer countries of the continent. Children are also used as unskilled labour and in the entertainment sector.

An estimated 8.4 million children work under terrible circumstances and are forced into bondage or other forms of slavery (Fig. 19).

Making children safe requires creating a protective environment for them. The key elements of a protective environment include:

- Strengthening the capacity of families and communities to care for and protect children.
- Government commitment to child protection by providing budgetary support and social welfare policies targeted at the most excluded and invisible children.
- Ratification and implementation of legislation, both national and international, concerning children's rights and protection.
- Prosecution of perpetrators of crimes against children, and avoidance of criminalizing child victims.
- An open discussion by civil society and the media of attitudes, prejudices, beliefs and practices that facilitate or lead to abuses.
-- Ensuring that children know their rights, are encouraged to express them and are given vital life skills and information to protect themselves from abuse and exploitation.

-- Availability of basic social services to all children without discrimination.

-- Monitoring, transparent reporting and oversight of abuses and exploitation.

The key to building the protective environment is the responsibility of members of the society, by ensuring that children are not exploited. While families and the State have the primary responsibility for protecting children, ongoing and sustained efforts by individuals and organizations at all levels, are essential to break patterns of abuse.

UJJAWALA: “Ujjawala”, a comprehensive scheme to combat trafficking was launched in India by the Ministry of Women and Child Development on 4th December, 2007 and is being implemented mainly through NGOs. The scheme has five components of prevention, rescue, rehabilitation, reintegration and repatriation of victims trafficked for commercial sexual exploitation. Some of the provisions under the scheme are (66):

1. Formation of community vigilance groups, adolescents groups, awareness creation and preparation of IEC material, organizing workshops;

2. Safe withdrawal of victims from the place of exploitation;

3. Rehabilitation of victims by providing them safe shelter, basic amenities, medical care, legal aid, vocational training and employment.

4. Re-integration of victims into society; and

5. Provide support to cross-border victims for their safe repatriation to the country of origin.

Child marriage

Early marriage is a long-established custom in India. As early as 1929, the Sharda Act was enacted forbidding the practice of child marriages. Inspite of the spread of literacy and legislations prohibiting early marriages, child marriages are still in vogue in the countryside particularly in Rajasthan, Madhya Pradesh and Uttar Pradesh, where substantial proportion of marriages take place when the girl is around 15 years of age (130). The census data reveal that prior to 1951, the average age at marriage for girls in India was 13 years. There is however a gradual rise in the age at marriage in the country. The Child Marriage Restraint Act of 1978 raises the legal age of marriage from 15 to 18 years for girls; and from 18 to 21 years for boys. Studies indicate that in many states, the mean age at marriage for girls has already moved into 19 years and 24 years for the boys. The Prohibition of Child Marriage Act, 2006 (PCMA) was enacted repealing the Child Marriage Restraint Act of 1929 in order to prohibit child marriage rather than only restraining them. PCMA has been enforced with effect from 1st November, 2007. It makes child marriage an offence and makes provision for punishment for those conducting / abetting /promoting / permitting the marriage (66).

The age at which the girl marries and enters the reproduction period of life has a great impact on her fertility. Girls who marry before the age of 18 give birth to larger number of children than those who married late. It is estimated that if the marriages were postponed from the age of 16 to 20-21, the number of births would decrease by 20-30 per cent.

Child guidance clinic

The first child guidance clinic was started in Chicago in 1909 and ever since, they have grown in number and complexity throughout the world. Originally intended to deal with problems of juvenile delinquency, child guidance clinics deal with all children or adolescents who for one reason or other, are not fully adjusted to their environment. The object of child guidance is to prevent children from the possibility of becoming neurotics and psychotics in later life.

Team work: Child guidance is a team work job – the team comprising of a psychiatrist, clinical psychologist, educational psychologist, psychiatric social workers, public health nurses, paediatrician, speech therapist, occupational therapist and a neurologist. The psychiatrist is the central figure and is helped by the others in arriving at a correct diagnosis and formulating the line of treatment.

Services: The paediatrician takes care of the physical health of the child. The core of therapy is psychotherapy in order to restore positive feelings of security in the child. To achieve this, many methods are employed, e.g., play therapy, counselling, suggestions, change in the physical environment, easing of parental tensions, reconstruction of parental attitudes, etc. The child guidance clinics operate on the premise that if sound foundations of mental health are laid in childhood and adolescence, the same will continue into adulthood.

Child placement

(1) ORPHANAGES: Children who have no home or who for some reason could not be cared for by their parents are placed in orphanages. Scientific studies of human behaviour have revealed that mass care of infants and children in large institutions is undesirable. In such institutions, there is little opportunity for the child to experience the warmth and intimacy of family life, to develop emotional security and to participate in activities that would help him to become an adequate citizen. (2) FOSTER HOMES: Fostering is an arrangement whereby a child lives, usually on a temporary basis, with an extended or unrelated family member. Such an arrangement ensures that the birth parents do not lose any of their parental rights or responsibilities. This arrangement can be adopted by children who are not legally free for adoption, and whose parents are unable to care for them due to illness, death or desertion by one parent, or any other crisis. The aim is to eventually re-unite the child with his/her own family, when the family circumstances improve (65). (3) ADOPTION: In addition to the more or less temporary placement of children in foster or boarding homes, children are legally adopted. Legal adoption confers upon the child and adoptive parents, rights and responsibilities similar to that of natural parents. The laws of adoption vary from country to country; the relevant law in India is the “Hindu Adoptions and Maintenance Act, 1956”.

(4) BORSTALS: Boys over 16 years who are too difficult to be handled in a certified school or have misbehaved there, are sent to a Borstal. This institution falls in a category between a certified school and an adult prison. A Borstal sentence which is usually for three years, is regarded as a method of training and reformation. There are about six Borstals for boys in India but none for girls. Borstals do not come under the Children Act but are governed by the State Inspector...
General of Prisons (131). (5) REMAND HOMES: In the
remand home, the child is placed under the care of doctors,
psychiatrists and other trained personnel. Every effort is
made to improve the mental and physical well-being of the
child. Elementary schooling is given, various arts and crafts
are taught, games are played and other recreational
activities are arranged.

THE CHILDREN ACT, 1960

The Children Act, 1960 in India (amended in 1977)
provides for the care, maintenance, welfare, training,
education and rehabilitation of the delinquent child. It
covers the neglected and destitute, socially handicapped,
uncontrollable, victimized and delinquent children. In Article
39 (f) the Constitution of India provides that "the state shall
in particular direct its policy towards securing that childhood
and youth are protected against moral and material
abandonment."

JUVENILE JUSTICE ACT 1986

With the implementation of the Juvenile Justice Act,
1986, all Children's Acts applicable in different parts of the
country have been repealed. The new Act, apart from
rectifying the inadequacies of Children's Act, provides a
comprehensive scheme for care, protection, treatment,
development and rehabilitation of delinquent juveniles. The
new Act has come into force from 2nd Oct 1987. Some of
the special features of the Act are :

- It provides a uniform legal framework for juvenile
  justice in the country so as to ensure that no child under
  any circumstances is put in jail or police lock-up;
- It envisages specialized approach towards prevention
  and treatment of juvenile delinquency in keeping with
  the developmental needs of children;
- It establishes norms and standards for administration
  of juvenile justice in terms of investigation, care,
  treatment and rehabilitation; and
- It lays down appropriate linkages and coordination
  between the formal system of juvenile justice and
  voluntary organizations. It specifically defines the
  roles and responsibilities of both.

Juvenile Justice Act 2000 (65)

Juvenile Justice (Care and Protection of Children) Act,
2000 (now Amendment Act 2006) is an Act to consolidate
and amend the law relating to juveniles in conflict with law
and children in need of care and protection, by providing for
proper care, protection and treatment by catering to their
developmental needs, and by adopting a child-friendly
approach in the adjudication and disposition of matters in
the best interest of children and for their ultimate
rehabilitation. The Act defines a juvenile/child as a person
who has not completed the age of 18 years. It has two
separate chapters — one for juveniles in conflict with law and
the other for children in need of care and protection. It also
contains an exclusive chapter concerning rehabilitation and
social reintegration of children. The Act defines Juvenile in
conflict with law as a child who is alleged to have committed
an offence and Children in need of care and protection
broadly as children who are neglected, abused, abandoned,
victim of any armed conflict or natural calamity amongst
others. Offences committed against a child as listed in the
Act, are cognizable and punishable under the provisions of
this Act.

Juvenile Justice (Care and Protection of
Children) Act 2015

Juvenile Justice (Care and Protection of Children) Act
2015 came into force from January 15, 2016. The Act allows
children aged 16 to 18 years and in conflict with law to be tried
as adults in cases of heinous offences. When pronounced
guilty, such children can be detained in a place of safety until
they reach the age of 21 years. If still not found to have
reformed by 21, they can be sent to jails housing adults.

SOCIAL WELFARE PROGRAMMES

The various social welfare programmes for women and
children in India may be broadly categorized under six
heads : (1) programmes for the welfare of women;
(2) programmes for the welfare of children; (3) composite
programmes (both for women and children); (4) schemes for
the maladjusted groups; (5) schemes for the physically
handicapped persons; and (6) programmes for the welfare of
backward classes

CHILD WELFARE

Child welfare covers the entire spectrum of needs of
children who by reason of handicap — social, economic,
physical or mental — are unable to avail of services provided
by the community (133). Child welfare programmes thus
seek to provide supportive services to the families of these
children because one of the important responsibility of the
society and state is to assist the family in its natural
obligations for the welfare of the children.

Child welfare services in their various facets are
preventive, promotive, developmental and rehabilitative in
nature. The problem is gigantic, and the resources available
are only supplementary in nature and are designed to meet
certain needs of the most deprived and vulnerable among
country's child population. Attention is generally focussed
on 3 categories of children in the poverty groups : children
of working mothers; destitute children, and handicapped
children (133).

CHILD WELFARE AGENCIES

The important child welfare agencies in India are :
(1) Indian Council for Child Welfare (ICCW); (2) Central
Social Welfare Board; (3) Kasturba Gandhi Memorial Trust,
and (4) the Indian Red Cross Society. These agencies have
got branches all over the country. They get financial aid
from the government to organize child welfare services in
the country. The following are some of their activities.
(a) DAY CARE SERVICES: This is for children of working mothers. Nursery schools, BALWADIS and creches are set up to help the children of working mothers. Day care centres are mainly for infants and toddlers. (b) HOLIDAY HOMES: These are organized for children in the age group 12 to 16 years at hill stations and sea-side resorts. The children spend their holidays in a useful manner. (c) RECREATION FACILITIES: These comprise organization of play centres, public parks, children's libraries, BAL BHAVANS, children's films, national museums, hobby classes, etc. Besides the national agencies, the following international agencies are interested in child welfare: UNICEF, WHO, International Union for Child Welfare, CARE and FAO of the United Nations.

INTEGRATED CHILD DEVELOPMENT SERVICES (ICDS)

Currently, the most important scheme in the field of child welfare is the ICDS scheme. The blueprint for the scheme was prepared by the Department of Social Welfare in 1975. Considering the magnitude of the task, it was decided to take up on an experimental basis 33 projects in the year 1975-76 in 4 urban, 19 rural and 10 tribal areas spread over 22 states and the Union Territory of Delhi. The projects were sanctioned in October 1975. The Government of India decided to expand the project to cover 100 areas by 1978-79. Two major evaluations were conducted in 1978 and 1982. The positive results of these evaluations formed the basis for the governments decision to accelerate the expansion of ICDS in 1982.

Prior to 2005-06, providing supplementary nutrition was the responsibility of the states and administrative cost was provided by the central government. Government of India has modified the cost sharing pattern under ICDS by giving aid of 50 per cent of the financial expenditure to the states/UTs.

The population norms for setting up of Anganwadi Centres (AWC) and Mini-AWC have been revised to cover all habitations by SC/ST/minorities. The revised norms are as follows (129):

For AWCs in rural/urban projects

1 AWC for 400-800 population
2 AWCs for 800-1600 population
3 AWCs for 1600-2400 population

Thereafter one AWC for multiples of 800 population. For Mini-AWC, the norm is one mini-AWC for 150 to 400 population.

Anganwadi on demand – where a settlement has at least 40 children under 6 years but no anganwadi centre.

For tribal/reverine/desert/hilly and other difficult areas

1 AWC for 300-800 population
1 Mini – AWC for 150-300 population.

The ICDS seeks to lay a solid foundation for the development of the nation's human resource by providing an integrated package of early childhood services. These consist of - (1) supplementary nutrition; (2) immunization; (3) health check-up; (4) medical referral services; (5) nutrition and health education for women; and (6) non-formal education of children up to the age of 6 years, and pregnant and nursing mothers in rural, urban, slums and tribal areas. ICDS scheme is designed both as a preventive and development effort. The services of immunization, health check-up and referral services are provided through public health infrastructure i.e., sub-centres, PHC and CHC. The services are provided concurrently.

Objectives (132)

The objectives of the ICDS scheme are:

(a) to improve the nutritional and health status of children in the age group 0–6 years;
(b) to lay the foundations for proper psychological, physical and social development of the child;
(c) to reduce mortality and, morbidity, malnutrition and school drop-out;
(d) to achieve an effective coordination of policy and implementation among the various departments working for the promotion of child development;
and
(e) to enhance the capability of the mother and nutritional needs of the child through proper nutrition and health education.

To achieve the above objectives the ICDS aims at providing the following package of services.

<table>

Source: (132)

The strategy adopted in ICDS is one of simultaneous delivery of early childhood services. While the health component forms a major component, ICDS is much more than a mere health programme for delivery of social services input for development.

Delivery of services

1. Supplementary nutrition

Supplementary nutrition is given to children below 6 years, and nursing and expectant mothers from low income group. The type of food depends upon local availability, type of beneficiary, location of the project etc. The aim is to supplement nutritional intake as follows (134):

- a. each child 6–72 months of age to get 500 calories and 12-15 grams of protein (financial norm of Rs 6.00 per child per day);
b. Severely malnourished child 6-72 months to get 800 calories and 20-25 grams protein (financial norm of Rs 9.00 per child per day); and

c. Each pregnant and nursing woman to get 600 calories and 18-20 grams of protein (financial norm of Rs 7.00 per beneficiary per day.

Under the revised nutritional and feeding norms for supplementary nutrition, state governments/UTs have been mandated to provide more than one meal to the children who come to AWCs, which include providing a morning snack in the form of milk/banana/egg/seasonal fruit/micronutrient fortified food followed by a hot cooked meal. For children below 3 years of age, and pregnant and lactating mothers, “take home ration” is to be provided. All are eligible for availing of the services of ICDS, below poverty line is not a criteria for registration of beneficiaries. The scheme is universal.

Supplementary nutrition is given 300 days in a year (132). Adequate funds for supplementary nutrition is provided in the State Plan under Minimum Needs Programme. Children are weighed every month. Nutrition education and health education is given to mothers of children suffering from 1st degree of malnutrition. Supplementary nutrition (therapeutic food) is given to children suffering from 2nd and 3rd degree of malnutrition. Children suffering from 4th degree malnutrition are recommended hospitalization.

2. Nutrition and health education

Nutrition education and health education is given to all women in the age group 15-45 years, giving priority to nursing and expectant mothers. It is imparted by specially organized courses in village during home visits by anganwadi workers.

3. Immunization

Immunization of children against 6 vaccine preventable diseases is being done, while for expectant mothers, immunization against tetanus is recommended.

4. Health check-up

This includes (a) antenatal care of expectant mothers; (b) postnatal care of nursing mother and care of newborn infants; (c) care of children under 6 years of age. Besides Immunization, expectant mothers are given iron and folic acid tablets along with protein supplements. A minimum of 3 physical examinations are done. High risk mothers are referred to appropriate institutions for special care.

The health care of children under 6 years of age consists of:

1. Record of weight and height of children at periodic intervals;
2. Watch over milestones;
3. Immunization;
4. General check-up every 3-6 months to detect disease, malnutrition etc.;
5. Treatment for disease like diarrhoea, dysentery, respiratory tract infections etc. which are widely prevalent;
6. Deworming;
7. Prophylaxis against vitamin A deficiency and anae mia; and
8. Referral of serious cases to hospital has also been provided for.

Health records : Health records of the children, antenatal care and delivery card etc. are maintained. A card containing the health record of the child is given to the mother.

5. Non-formal pre-school education

Children between the ages 3-6 years are imparted non-formal pre-school education in an anganwadi in each village with about 1000 population. The objective is to provide opportunities to develop desirable attitude, values and behaviour pattern among children. Locally produced inexpensive toys and material are used in organizing play and creative activity.

Schemes for adolescent girls (66)

At present, there are two schemes for adolescent girls viz. “Kishori Shakti Yojana” and “Nutrition Programme for Adolescent Girls”.

Kishori Shakti Yojana is being implemented using the infrastructure of ICDS. The scheme targets adolescent girls in the age group of 11 to 18 years and addresses their needs of self development, nutrition and health status, literacy and numerical skills, vocational skills etc.

Nutrition Programme for Adolescent Girls was approved in the year 2009-10, on a pilot project basis. The project is being implemented in 51 identified districts from the major states. Undernourished adolescent girls in the age group of 11 to 19 years (with body weight less than 30 kg in the age group of 11 to 15 years and 35 kg in the age group of 15 to 19 years) are covered under the scheme, 6 kg of free food grain is provided to each beneficiary per month. The programme is being implemented through the administrative set-up of ICDS scheme at the state, district, block and Anganwadi Centre level.

Two more schemes are being implemented at the ICDS level. They are (a) Rajiv Gandhi Scheme for Empowerment of Adolescent Girls – “SABLA” for the age group 11 to 18 years to improve their nutritional and health status; and (b) Indira Gandhi Matiinaa Sahyog Yojana (IGMSY), under which conditional cash transfer will be made to pregnant and lactating mothers in order to improve their nutritional and health status (66).

At the end of 2014, about 7,067 ICDS projects and 13.42 lakh Anganwadi Centres/Mini-Anganwadi Centres were functional in the country. About 104,100 children and pregnant and lactating mothers are getting the benefit of the scheme.

The administrative unit of an ICDS project is the “community development block” in rural areas, the “tribal development block” in tribal areas and a group of slums in urban areas. In selection of project areas preference was given to areas predominantly inhabited by backward tribes, backward areas, drought prone areas and areas in which nutritional deficiencies are rampant. The rural/urban project has a population of 100,000 and a tribal project about 35,000 population. The number of villages in the rural project may be 100 while in tribal areas, it may be only about 50, taking into account the difficult terrain in which the tribal projects are located. The focal point for the delivery of integrated early childhood services under the ICDS scheme is the trained local woman known as Anganwadi worker (AWW). Other functionaries in the ICDS are the Child Development Project Officer (CDPO), who is in charge of 4 Supervisors (Mukhya Sevika) and 100 AWWs.
Each Supervisor is responsible for 20–25 anganwadis and acts as mentor to AWWs; assists in record keeping, visits of health personnel and organizing community visits; and provides on-the-job training to AWWs. Anganwadi worker is the multipurpose agent, selected from the community. AWW provides direct link to children and mother; assists CDPO in survey of community and beneficiaries; organizes non-formal education sessions; provides health and nutrition education to mothers; assists PHC staff in providing health services; maintains records of immunization, feeding and pre-school attendance; liaises with block administrator, local school, health staff and community, and works for other community-based activities, e.g., family planning.

The Government of India is committed to child development as a policy priority and is steadily expanding ICDS programme with the ultimate aim of reaching every child. The impact of the programme on the lives of children is evident in several crucial indicators—increased birth weight, reduced incidence of malnutrition, increased immunization coverage, and a reduced infant and child mortality rate in areas covered by the ICDS (116).

Health of adolescents

The term “adolescence” has been defined as including those aged between 10 and 19, and “youth” as those between 15 and 24; “young people” is a term that covers both age groups, i.e., those between the ages of 10 and 24. True adolescence, however, being the period of physical, psychological, and social maturing from childhood to adulthood, may fall within either age range. The development that takes place in adolescence is generally uneven, in that physical maturity may well be achieved in advance of psychological or social maturity; in most societies, in fact, reproductive capability is now established at an earlier age than in the past.

The importance of the health of adolescents has started to receive increasing recognition, particularly in developing countries where four out of five of the world’s young people live, and where more than half the population is under the age of 25. These young men and women are, or will become, the parents of the next generation. They must be given every opportunity to develop to their full potential as healthy individuals.

Because adolescents are less vulnerable to disease than the very young and the very old, health problems specific to their age group have been given little prominence until now. Moreover, in societies where girls in particular have traditionally married at an early age, adolescence has been regarded merely as a brief interlude between puberty and marriage. As the average age of menarche has fallen, and with an increasing trend towards late marriage, however, this period has been extended and traditional attitudes have begun to change. At the same time, the influence of the family has declined, urbanization and migration have become more common, and young people have been increasingly exposed to the mass media—all factors that contribute to major changes in social and sexual behaviour.

High rate of mortality and morbidity has always been associated with pregnancy and childbirth in pubertal and adolescent girls. This problem is now compounded by the dramatic rise in the number of pregnancies, both wanted and unwanted, among adolescents, who are also having more abortions and contracting sexually transmitted diseases more often. There appears also to be an increase in the number of abandoned and abused children born to adolescent mothers. As long as these problems are allowed to persist, much of the energy, creativity and idealism of youth will be lost to society. However, the problems are preventable, and efforts to eliminate them must involve the young people themselves, contributing in ways appropriate to their particular cultures.

Society today demands more of young people than ever before. With the decline of the extended family greater autonomy is expected of them, especially in the raising of children; increasing urbanization and industrialization means that economic independence is achieved only through more education and training. Early parenthood, particularly for girls, may limit or preclude social and educational development and the ability to achieve full status in society and is associated with greater morbidity and mortality. The World Fertility Survey observed an inverse relationship between fertility and the education of women: women with no education have, on average, twice as many children as those with seven or more years of schooling. Corollaries of this finding are the increased earning power of educated women, their improved status within the family, and the greater control they are able to exercise over their own lives.

A more universal consequence of early and more frequent childbearing is the increase in population size and growth rate. Where girls marry at 15, the age gap between successive generations may be less than 20 years; this gap may widen to as much as 30 years when the age at marriage is 25. The sexual behaviour and reproductive patterns of young people are highly susceptible to social influences and related to their own sense of psychological well-being.

Although an adolescent girl is likely to give birth and rear her children within the context of an extended family, the risks she and her children run of illness, injury and death are far greater than those for a mature woman in her twenties. The chances of anaemia, developing during pregnancy, and of retarded fetal growth; premature birth and complications during labour are all significantly higher for the adolescent mother, as are the risks of her own death during pregnancy or child-birth.

Formal education of girls generally ends with marriage, and from then on their social status may well depend on fecundity. An adolescent girl who proves to be infertile (or whose husband is infertile) runs the risk of being rejected by both husband and family and thus of losing what little status she has. The second major set of problems of reproductive health in adolescence results from the profound socio-economic changes taking place in most developing countries. The average age of menarche has fallen, there is a trend towards later marriage, and young people are often less directly supervised than was the case in the past—all of which have the effect of increasing the opportunities for sexual encounter. Since the subject of adolescent sexuality remains taboo in most societies, there is widespread ignorance among young people of the risks associated with unprotected sexual activity. Sources of information and contraceptive advice are rarely available or accessible to them. In addition, impulsive sexual behaviour and non-use of contraceptives are sometimes exacerbated by alcohol and drug abuse.

A number of major approaches to reducing problems by modification of the contributing factors will serve to promote
good health among the young and thus to improve health
and social development of their communities. These
approaches include the following:

1. Informing, educating and sensitizing key groups in
society to individual health and social development
needs
2. Advocating appropriate policy, legislation and
programmes for promoting adolescent reproductive
health.
3. Using appropriate and innovative research to improve
knowledge of, and disseminate information about, the
factors that influence and determine young people’s
sexual, contraceptive and reproductive decisions and
behaviour
4. Modifying, extending and evaluating services specially
designed to meet young people’s needs.
5. Mobilizing the energy, creativity and idealism of young
people in promoting health and developing
appropriate activities in their communities.
6. Facilitating action to extend education opportunities
for girls

PREVENTIVE MEDICINE AND GERIATRICS

Ageing is a natural process. In the words of Seneca; “Old
age is an incurable disease”, but more recently, Sir James
Sterling Ross commented: “You do not heal old age. You
protect it; you promote it; you extend it” (135). These are in
fact the basic principles of preventive medicine. Old age
should be regarded as a normal, inevitable biological
phenomenon. The study of the physical and psychological
changes which are incident to old age is called gerontology.
The care of the aged is called clinical gerontology or
geriatrics. Another aspect of gerontology is social
gerontology which was born on the one hand out of the
instincts of humanitarian and social attitudes and on the
other out of the problems set by the increasing number of
old people (136). Experimental gerontology is concerned
with research into the basic biological problems of ageing,
into its physiology, biochemistry, pathology and psychology.
The fields of studies range from studies of populations
through individuals, organs, systems, tissues and cells, down
to the molecular level. GERIATRIC GYNAECOLOGY: With
the lengthening span of life a new chapter in gynaecology —
geriatric gynaecology — is fast opening up. More patients are
coming for repair of prolapse of varying degrees, non-
-specific vaginitis, ovarian tumours, psychic aberrations and
sexual problems. There is ample scope for research into
the degenerative and other diseases of old age; their
problems due to the ageing process

(1) PROBLEMS DUE TO THE AGEING PROCESS

No one knows when old age begins. The “biological age”
of a person is not identical with his “chronological age”. It is
said that nobody grows old merely by living a certain number
of years. Years wrinkle the skin, but worry, doubt, fear,
anxiety and self-distrust wrinkle the soul. While ageing merely
stands for growing old, senescence is an expression used for
the deterioration in the vitality or the lowering of the
biological efficiency that accompanies ageing. With the
passage of time, certain changes take place in an organism.
These changes are, for the most part deleterious and
eventually lead to the death of the organism. Our knowledge
about the ageing process is incomplete. We do not know
much about the disabilities incident to the ageing process.
However the following are some of the disabilities considered
as incident to it; (a) senile cataract, (b) glaucoma, (c) nerve
defauness, (d) osteoporosis affecting mobility, (e) emphysema
(f) failure of special senses, (g) changes in mental outlook.
This list is not exhaustive; we need to know a lot more about
the disabilities incident to the ageing process.

(2) PROBLEMS ASSOCIATED WITH LONG-TERM
ILLNESS

Certain chronic diseases are more frequent among the
older people than in the younger people. These are:
(a) DEGENERATIVE DISEASES OF HEART AND BLOOD
VESSELS: Of particular importance after the age of 40, are
the degenerative diseases of the heart and blood vessels.
The inner walls of arteries break down, and a lipoid material
is deposited. This in time is replaced by calcium which leads
to diminished blood supply, thrombus formation, rupture of
blood vessels and high blood pressure. No single factor has
been identified as the cause of atherosclerosis. Diet,
heredity, overweight, nervous and emotional strain have all
been implicated. Cardiovascular diseases are the major
causes of death in the developed countries. A reduction of
body weight and modification of the habits of life are
needed to decrease the strain on heart and blood vessels. By
these, it is possible to lead a longer and more useful life.
(b) CANCER: The danger of cancer looms large past middle
life. In the developed countries, cancer is a leading cause of
death. The incidence of cancer rises rapidly after the age of
40. Cancer of the prostate is common after the age of 65.
(c) ACCIDENTS: Accidents are a health problem in the
elderly. The bones become fragile due to a certain amount
of decalcification as a result of which they break easily.
Accidents are more common in the home than outside.
Fracture neck of femur is a very common geriatric problem.
(d) DIABETES: Diabetes is a long-term illness due to faulty carbohydrate metabolism. It is a leading cause of death as the population grows older. About 75 per cent of the diabetics are over 50 years of age. (e) DISEASES OF LOCOMOTOR SYSTEM: A wide range of articular and non-articular disorders affect the aged – fibrositis, myositis, neuritis, gout, rheumatoid arthritis, osteoarthritis, spondylitis of spine, etc. These conditions cause more discomfort and disability than any other chronic disease in the elderly. (f) RESPIRATORY ILLNESSES: In the upper decades of life, respiratory diseases such as chronic bronchitis, asthma, emphysema are of major importance. (g) GENITOURINARY SYSTEM: Enlargement of the prostate, dysuria, nocturia, frequent and urgency of micturition are the common complaints.

(3) PSYCHOLOGICAL PROBLEMS

(1) MENTAL CHANGES: Impaired memory, rigidity of outlook and dislike of change are some of the mental changes in the aged. Reduced income leads to a fall in the living standards of the elderly; it does have mental and social consequences. (2) SEXUAL ADJUSTMENT: Between 40 and 50, there is a cessation of reproduction by women and diminution of sexual activity on the part of men. During this phase, physical and emotional disturbances may occur. Irritability, jealousy and despondency are very frequent. (3) EMOTIONAL DISORDERS: Emotional disorders result from social maladjustment. The degree of adaptation to the fact of ageing is crucial to a man's happiness in this phase of life. Failure to adapt can result in bitterness, inner withdrawal, depression, weariness of life, and even suicide.

Lifestyle and healthy ageing

People can do a great deal to influence their individual risk of developing many of the diseases of later life by paying careful attention to lifestyle factors. By adopting a healthier lifestyle, the risk of a whole range of diseases can be reduced. These factors are: (a) DIET AND NUTRITION: A good diet reduces the chances of developing the diseases of old age. As countries rapidly develop economically, diets and lifestyles change considerably and overnutrition replaces undernutrition. One of the problems is excessive fat intake. Saturated fats and trans-fatty acids, have been linked to raised cholesterol levels in the blood, leading to increased risk of cardiovascular diseases. People should eat healthy diet since very early age to avoid or delay diseases. The diet should be balanced with less saturated fats and oils; should contain lots of fruits and vegetables; salt and sugar should be less; include plenty of calcium rich food; eat high fibre diet; (b) EXERCISE: Exercise helps maintain good health, as it helps to control weight, improves emotional well-being and relieves stress, improves blood circulation, increases flexibility, lowers blood pressure, increases energy levels, improves balance and thus reduces the dangers of falls, lowers blood sugar levels thus helps in diabetes, improves bone density and thus helps prevent osteoporosis; (c) WEIGHT: Overweight and obesity have become major problem worldwide and it contributes to many diseases of later life. Obesity is an important factor in heart disease, stroke, hypertension, diabetes, arthritis (especially in the knees), and breast cancer; (d) SMOKING: It is estimated that 22 per cent of men and 18 per cent of women aged 65 to 74 years in developed countries are smokers (137). Though this figure is lower than among younger adults, older people have usually smoked for longer, have been and continue to be heavy smokers, and are likely to have chronic diseases, with smoking causing further deterioration. Former smokers live longer than continuing smokers; smoking cessation at the age of 50 years reduces the risk of dying within the next 15 years by 50 per cent. For some, but not for all former smokers, the risk of developing smoking-related diseases reverts to that of lifelong non-smokers (137); (e) ALCOHOL: Drinking beyond a specified amount contributes to a number of later life diseases. Research suggests that sensitivity to the effect of alcohol increases with age. Older people achieve a higher blood alcohol concentration, than younger people after consuming an equal amount of alcohol. This is largely as a result of the age-related decrease in the amount of body water which dilutes alcohol. While younger people are likely to develop tolerance to increasing amount of alcohol, older people have a decreased ability to develop this tolerance (137). Drinking is linked to liver diseases, stomach ulcers, gout, depression, osteoporosis, heart disease, breast cancer, diabetes and hypertension (138); and (f) SOCIAL ACTIVITIES: People who become socially isolated — who rarely go out, do not join in the community activities, have few friends or do not see much of their family are less healthy. Getting out and keeping involved with others creates a sense of belonging. Mixing with other people of similar age, at similar stage of life or perhaps with similar health concerns, can help people realize that they are not alone. The support gained from others can be important in recovering from illness. Simply knowing that others care, helps (136).

Health status of the aged in India

A few hospital based studies have been made in India on the health status of the aged persons, but such studies provide only a partial view of the spectrum of illness in the aged. The overall data on aged are scarce. The main causes of illness are arthritis, cataract, bronchitis, avitaminosis, ear diseases, hypertension, diabetes, rheumatism, helminthic infestations, accidents, etc.

The government of India announced a National Policy on older persons in January 1999. This policy identifies principal areas of intervention as financial security, health care, nutrition, shelter, education, welfare, protection of life and property of older citizens. The policy provides for a broad framework for collaboration and cooperation, both within as well as between governmental and non-governmental agencies. An important thrust in the policy is on active and productive involvement of older persons, and not just their care. A national council for older persons (NCOP) was constituted to operationalize the policy. An integrated programme for older persons has been formulated by revising the earlier scheme of assistance to voluntary organizations for programmes relating to the welfare of the aged. The objective is to promote a society for all ages, to empower and improve the quality of life of older persons.

The programme for the first time recognizes formation of self-help groups, association of older persons for advancement of their rights and utilization of their experience and services. 234 Old age homes, 398 day care centres and 40 mobile medical units are operational. Scheme of assistance to Panchayat Raj Institutions /
Voluntary Organizations / Self Help Groups, for construction of old age homes has also been revised to encourage Multi Service Centres for older persons.

As a part of National Social Assistance Programme, old age pension is being provided to more than 4 million destitute elderly all over the country. The amount of pension varies from state to state – from Rs 75 per month in Assam to Rs 300 per month in West Bengal and Rajasthan (137). An Old Age Social and Income Security (OASIS) project was launched to comprehensively examine policy questions, connected with Old Age Income Security. Travel related concessions / facilities are provided to the older people by Indian Railways, Indian Airlines and State Transport Corporations. Health care is being provided to the older persons through Bhavishya Arogya Mediclaim, and Rural Group Life Insurance Schemes. Income Tax Concessions are also available to the elderly citizens.

On 19th Nov, 2007, the Indira Gandhi National Old Age Pension Scheme was launched to provide monthly pension to people over 65 years and living below poverty line. The scheme is to cover about 1.57 crore people, the central government is to provide a monthly pension of Rs. 200 to each beneficiary and the state governments are expected to contribute an equal amount.

In India, HelpAge India is the largest voluntary organization working for the cause and care of the disadvantaged older people. In the 26 years since its inception, it has made an impact on the lives of nearly 6 million senior citizens, through 3,084 projects. HelpAge India supports the following programmes to make life easier for older people: (a) Free cataract operations; (b) Mobile medicare units; (c) Income generation and micro-credit; (d) Old-age homes and day-care centres; (e) Adopt-a-Gran (grand parent); and (f) Disaster mitigation.

**Implication of the ageing population in terms of preventive and social medicine**

The ageing population is both a medical and sociological problem. It makes a greater demand on the health services of a community. In rapidly grey ing world, healthy ageing is vital for countries. It is a prerequisite for economic growth. The predicted explosion of non-communicable diseases like cardiovascular diseases, cancer, and depression in the ever increasing number of older persons globally, will result in enormous human and social costs unless preventive action is taken.

The alteration of the age pyramid, however, poses significant new challenges for governments, societies, and families in the 21st century. Ageing developing countries are slated to face a heavy double burden of infectious and non-communicable diseases, yet they often lack significant resources, including comprehensive ageing policies, to cope. Industrialized countries, on the other hand, were fortunate enough to become affluent before they became old (137).

The modern philosophy is that the old must continue to take their share in the responsibilities and in the enjoyment of the privileges, which are an essential feature of remaining an active member of the community. The community must assist the aged to fight the triple evils of poverty, loneliness and ill-health.

**Potential for disease prevention in the elderly**

For older individuals, a great proportion of the disease burden derives from existing conditions, whether this burden is measured by prevalence rates, indicators of morbidity, disability, mortality, or by health and long term care utilization. In addition, older people with disability, resulting from chronic diseases, appear at high risk of acute illness and injuries. The evidence arrayed of the role of existing and often immutable disease argues for the importance of secondary and tertiary prevention, in combination with primary screening or prevention for this population (139).

Among older individuals, categories of conditions, occurrences, and illnesses exist in a variety of combinations, and risk factors as well as disease sequelae often overlap. Examples of conditions potentially amenable to prevention in older persons are outlined in Table 32.

Many factors that contribute to decrements of ageing and the burden of illness are potentially responsive to preventive interventions. In view of this evidence, the design of preventive strategies appropriate to this population becomes crucial for the utility of preventive care, both in reducing risk and maintaining functional independence.

Much care is bestowed upon the old people in Western societies by providing Social Welfare measures such as national assistance, supplementary pensions, home services, meals on wheels services, old folk’s homes, sitters-up service and provision of services of health visitors. By providing these services, the State ensures that the years of retirement of those who have worked hard in its service shall be free from anxiety, want and boredom.

**TABLE 32**

Areas potentially amenable to preventive health care in the elderly

Source: (139)
IMCI clinical guidelines are based on the following principles:

1. Examining all sick children aged up to five years of age for general danger signs and all young infants for signs of very severe disease. These signs indicate severe illness and the need for immediate referral or admission to hospital.

2. The children and infants are then assessed for main symptoms:
   - In older children, the main symptoms include:
     - Cough or difficulty in breathing
     - Diarrhoea
     - Fever
     - Ear infection
   - In young infants, the main symptoms include:
     - Local bacterial infection
     - Diarrhoea
     - Jaundice

3. Then in addition, all sick children are routinely checked for:
   - Nutritional and immunization status
   - HIV status in high HIV settings
   - Other potential problems

4. Only a limited number of clinical signs are used, selected on the basis of their sensitivity and specificity to detect disease through classification.

A combination of individual signs leads to a child's classification within one or more symptom groups rather than a diagnosis. The classification of illness is based on a colour-coded triage system:
   - "PINK" indicates urgent hospital referral or admission
   - "YELLOW" indicates initiation of specific outpatient treatment
   - "GREEN" indicates supportive home care

5. IMCI management procedures use a limited number of essential drugs and encourage active participation of caregivers in the treatment of their children.

6. An essential component of IMCI is the counselling of caregivers regarding home care:
   - Appropriate feeding and fluids
   - When to return to the clinic immediately, and
   - When to return for follow-up

---

**SICK YOUNG INFANT AGE UPTO 2 MONTHS**

**ASSESS**

DO A RAPID APPRAISAL OF ALL WAITING INFANTS

ASK THE MOTHER WHAT THE YOUNG INFANT'S PROBLEMS ARE:

- Determine if this is an initial or follow-up visit for this problem.
  - If follow-up visit, use the follow-up instructions
  - If initial visit, assess the child as follows

**CLASSIFY**

USE ALL BOXES THAT MATCH THE INFANT'S SYMPTOMS AND PROBLEMS TO CLASSIFY THE ILLNESS

**IDENTIFY TREATMENT**

- Give first dose of intramuscular antibiotics
- Treat to prevent low blood sugar
- Refer URGENTLY to hospital
- Advise the mother how to keep the infant warm on the way to the hospital

---

**CHECK FOR VERY SEVERE DISEASE AND LOCAL BACTERIAL INFECTION**

ASK:

- Is the model having continuous, in feeding?
- Has the infant had convulsions before?

LOOK, LISTEN, FEEL:

- Count the breaths in one minute. Repeat if necessary per minute.
- Look for severe chest indrawing.
- Measure oral or rectal temperature.
- Look at the umbilicus. Is it red or draining pus?
- Look for skin pustules.
- Look at the young infant's movements. If infant is sleeping, ask the mother to wake him/her.
- Does the infant move on his/her own?
- If the young infant is not moving, gently stimulate him/her.
- Does the infant not move at all?

---

*These thresholds are based on axillary temperature. The fever is severe, if rectal temperature readings are approximately 0.5°C higher.
** If referral is not possible, manage the sick child as described in the national referral care guidelines or WHO Pocket Book for hospital care for children.
CHECK FOR JAUNDICE

| If jaundice present, ASK: | LOOK AND FEEL: | CLASS/ | CHECK FOR DEHYDRATION
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>- When did jaundice appear first?</td>
<td>- Look for jaundice. Yellow eyes or skin?</td>
<td>jaundice</td>
<td>- Look at the young infant’s general condition. Infant’s movements: - Does the infant move on his/her own? - Does the infant move when simulated but then stops? - Does the infant not move at all? - Is the infant restless and irritable?</td>
</tr>
<tr>
<td>- Palms and soles not yellow.</td>
<td>- Look at the young infant’s palms and soles. Are they yellow?</td>
<td>jaundice</td>
<td>Two of the following signs: - Restless and irritable. - Sunken eyes. - Skin pinch goes back slowly.</td>
</tr>
</tbody>
</table>
| | | jaundice | | |}

THEN ASK: Does the young infant have diarrhoea? 

**IF YES, LOOK AND FEEL**

<table>
<thead>
<tr>
<th>Two of the following signs:</th>
<th>Pink: SEVERE DEHYDRATION</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>- Diarrhoea present when stimulated (gives frequent sips of ORS). - Diarrhoea present when stimulated (gives frequent sips of ORS).</td>
<td>SEVERE DEHYDRATION</td>
<td>- If infant has no other severe classification: Check if infant has severe dehydration, if infant has no other severe classification: ORS</td>
<td>- If infant has any severe classification: - Refer urgently to hospital with mother giving frequent sips of ORS on the way. - Advise the mother to continue breast-feeding.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>- Advise the mother to return immediately. - Follow-up in 2 days if not improving.</td>
</tr>
</tbody>
</table>

**What is diarrhoea in a young infant?**

A young infant has diarrhoea if the stools have changed from a usual pattern and are more watery, move water than faecal matter.
The normally frequent or semi-solid stools of a breastfed baby are not diarrhoea.
THEN CHECK FOR FEEDING PROBLEM OR LOW WEIGHT FOR AGE
If an infant has no indications to refer urgently to hospital:

ASK:
- Is the infant breastfed? If yes, how many times in 24 hours?
- Does the infant usually receive any other drinks? If yes, how often?
- If yes, what do you use to feed the infant?

LOOK, LISTEN, FEEL:
- Determine weight for age
- Look for ulcers or white patches in the mouth
- Look for feeding problems or low weight for age

Classify FEEDING
- Yellow: FEEDING PROBLEM OR LOW WEIGHT
- Green: NO FEEDING PROBLEM
- Red: Not well attached
- Yellow: Feeding effectively, check for positioning and attachment.
- Green: Feeding effectively, check for positioning and attachment.
- Red: Not able to attach well
- Green: Not able to attach well

- If not well attached or not suckling effectively, teach the mother to express breast milk and feed by a cup
- If not breastfeeding at all:
  - Refer for breastfeeding counselling and possible relactation
  - Advice about correctly preparing breast milk substitutes and using a cup
  - Advise the mother how to feed and keep the low weight infant warm at home
  - If thrush, teach the mother to treat thrush at home
  - Advise the mother to give home care for the young infant
  - Follow-up any feeding problem or thrush in 2 days
  - Follow-up low weight for age in 14 days

- Unless breastfeeding because the mother is HIV positive:
  - Advise mother to give home care for the young infant
  - Praise the mother for feeding the infant well
SICK CHILD AGE 2 MONTHS UPTO 5 YEARS
ASSESS AND CLASSIFY THE SICK CHILD

### ASSESS

**ASK THE MOTHER WHAT THE CHILD’S PROBLEMS ARE**
- Determine if this is an initial or follow-up visit for this problem.
  - If follow-up visit, use the follow-up instructions on TREAT THE CHILD chart.
  - If initial visit, assess the child as follows:

### CHECK FOR GENERAL DANGER SIGNS

<table>
<thead>
<tr>
<th><strong>ASK</strong></th>
<th><strong>LOOK</strong></th>
<th><strong>URGENT Attention</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>- Is the child able to drink or breastfeed?</td>
<td>- See if the child is lethargic or unconscious</td>
<td>- Give dexamethasone if convulsing now</td>
</tr>
<tr>
<td>- Does the child vomit everything?</td>
<td>- Is the child convulsing now?</td>
<td>- Quickly complete the assessment</td>
</tr>
<tr>
<td>- Has the child had convulsions?</td>
<td></td>
<td>- Give any pre-referral treatment immediately</td>
</tr>
</tbody>
</table>

A child with any general danger sign needs URGENT attention; complete the assessment and any pre-referral treatment immediately so referral is not delayed.

### THE N MORE ABOUT MAIN SYMPTOMS

**Does the child have cough or difficult breathing?**

<table>
<thead>
<tr>
<th><strong>IF YES, ASK:</strong></th>
<th><strong>LOOK, LISTEN, FEEL:</strong></th>
<th><strong>Cough or Difficult Breathing</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>- For how long?</td>
<td>- Count the breaths in one minute.</td>
<td>CHILD MUST BE CALM</td>
</tr>
<tr>
<td></td>
<td>- Look for chest indrawing.</td>
<td></td>
</tr>
<tr>
<td></td>
<td>- Look and listen for wheezing</td>
<td></td>
</tr>
<tr>
<td></td>
<td>- If wheezing with either fast breathing or chest indrawing:</td>
<td></td>
</tr>
<tr>
<td></td>
<td>- Give a trial of rapid acting inhaled bronchodilator for up to three times 15-20 minutes apart. Count the breaths and look for chest indrawing again, and then classify.</td>
<td></td>
</tr>
<tr>
<td><strong>If the child is:</strong></td>
<td><strong>Fast breathing is:</strong></td>
<td></td>
</tr>
<tr>
<td>2 months up to 12 months</td>
<td>50 breaths per minute or more</td>
<td></td>
</tr>
<tr>
<td>12 months up to 5 years</td>
<td>40 breaths per minute or more</td>
<td></td>
</tr>
</tbody>
</table>

**If pulse oximeter is available, determine oxygen saturation and refer if < 90%.

**If referral is not possible, manage the child as described in the pneumonia section of the national referral guidelines or as in WHO Pocket Book for Hospital care for children.

**Oral Amoxicillin for 3 days could be used in patients with fast breathing but no chest indrawing in low HIV settings.

**In settings where inhaled bronchodilator is not available, oral salbutamol may be tried but not recommended for treatment of severe acute wheeze.
If the stool has blood:

- Give fluid, zinc supplements, and food for some dehydration (Plan B).
- If child also has a severe classification:
  - Refer URGENTLY to hospital with mother giving frequent sips of ORS on the way.
  - Advise the mother to continue breastfeeding.
- Advise mother when to return immediately.
- Follow-up in 5 days if not improving.

If child also has another severe classification:

- Refer URGENTLY to hospital with mother giving frequent sips of ORS on the way.
- Advise the mother to continue breastfeeding.
- Give fluid, supplements, and food for some dehydration and advise mother when to return.
- Follow-up in 5 days if not improving.

If stool is not formed:

- Give fluid, zinc supplements, and food for some dehydration (Plan B).
- Advise mother to give ORS to child every hour.
- Advise mother to continue breastfeeding.
- Follow-up in 5 days if not improving.
DOES THE CHILD HAVE FEVER?
(by history or feels hot or
temperature 37.5°C or above)

IF YES:
- Decide Malaria Risk
  High or Low

THEN ASK:
- Fever for how long?
- If more than 7 days, has fever been present every day?
- Has the child had measles within the last 3 months?

LOOK AND FEEL:
- Look or feel for stiff neck.
- Look for any bacterial cause of fever.
- Look for signs of MEASLES
  Generalized rash and One of these
  or enanthem more or or red eyes

IF YES:
- Decide Malaria Risk
  High or Low

Malaria test
- NO MALARIA
  Malaria test
- Yes MALARIA

IF YES:
- Look and feel for high fever:
  For how long?
- Look for any bacterial cause of fever.
- Give appropriate antibiotic
  7 days, has Look for runny nose, raptor.
- Give Vitamin A treatment
  When present every day for more than 7 days, refer for assessment.

If the child has measles now or within the last 3 months:
- Look for mouth ulcers. Are they deep and extensive?
- Look for pus draining from the eye
- Look for clouding of the cornea.

Do a malaria test***:
- NO MALARIA
  Malaria test
- NO MALARIA

If NO severe classification:
- In all fever cases if high malaria risk
- In Low malaria risk if no obvious cause of fever present.

No Malaria Risk and No Travel to Malaria Risk Area

High or Low Malaria Risk

**These temperatures are based on axillary temperature.
Rectal temperature readings are approximately 0.5°C higher.

** Look for local tenderness; oral sores; refusal to use a limb; hot tender swelling, red tender skin or boils, lower abdominal pain or pain on passing urine in older children.

*** If no malaria test available: High malaria risk - classify as MALARIA; Low malaria risk AND NO obvious cause of fever - classify as MALARIA.

**** Other important complications of measles - pneumonia, stridor, diarrhoea, ear infection, and acute malnutrition - are classified in other tables.
### Does the Child Have an Ear Problem?

**IF YES, ASK:**
- Is there ear pain?
- Is there ear discharge?
- If yes, for how long?

**LOOK AND FEEL:**
- Look for pus draining from the ear.
- Feel for tender swelling behind the ear.

**Classify Ear Problem**

<table>
<thead>
<tr>
<th>Color</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pink</td>
<td>Mastoiditis</td>
</tr>
<tr>
<td>Yellow</td>
<td>Acute Ear Infection</td>
</tr>
<tr>
<td>Green</td>
<td>No Ear Infection</td>
</tr>
</tbody>
</table>

- **Pink:**
  - Tender swelling behind the ear.
  - Give first dose of an appropriate antibiotic.
  - Give first dose of paracetamol for pain relief.
  - Refer URGENTLY to hospital.

- **Yellow:**
  - Pus is seen draining from the ear and discharge is reported for less than 14 days, or ear pain.
  - Give an antibiotic for 5 days.
  - Give paracetamol for pain relief.
  - Dry the ear by wicking.
  - Follow-up in 5 days.

- **Green:**
  - No ear pain and no pus seen draining from the ear.
  - Give paracetamol for pain relief.
  - Dry the ear by wicking.
  - Follow-up in 5 days.

### Then Check for Acute Malnutrition

**CHECK FOR ACUTE MALNUTRITION**

**LOOK AND FEEL:**
- Look for signs of acute malnutrition.
- Look for oedema of both feet.
- Measure MUAC** — mm in a child 6 months or older.
- If WFH/L less than -3 z-scores or MUAC less than 115 mm, then:

- Check for any medical complication present:
  - Any general danger signs.
  - Any severe classification.
  - Pneumonia with chest indrawing.

- If no medical complications present:
  - Child is 6 months or older, offer RUTF*** to eat.
  - Is the child able to finish RUTF portion?
  - Child is less than 6 months, assess breastfeeding.
  - Does the child have a breastfeeding problem?

**Classify Nutritional Status**

<table>
<thead>
<tr>
<th>Color</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pink</td>
<td>Complicated Severe Acute Malnutrition</td>
</tr>
<tr>
<td>Yellow</td>
<td>Uncomplicated Severe Acute Malnutrition</td>
</tr>
<tr>
<td>Green</td>
<td>No Acute Malnutrition</td>
</tr>
</tbody>
</table>

- **Pink:**
  - WFH/L less than -3 z-scores, or MUAC less than 115 mm AND at least one of the following:
    - Measle or other acute infections present or not able to finish RUTF.
    - Fever.
    - Breastfeeding problem.
  - Give oral antibiotics for 5 days.
  - Give ready-to-use therapeutic food for a child aged 6 months or more.
  - Counsel the mother on how to feed the child.
  - Assess for possible TB infection.
  - Advise mother when to return immediately.
  - Follow-up in 7 days.

- **Yellow:**
  - WFH/L between -3 and -2 z-scores or MUAC 115 up to 125 mm.
  - Able to finish RUTF.
  - Give paracetamol for pain relief.
  - Follow-up in 3 days.

- **Green:**
  - If child is less than 2 years old, assess the child's feeding and counsel the mother on the feeding recommendations.
  - If feeding problem, follow up in 7 days.
  - Assess for possible TB infection.
  - Advise mother when to return immediately.
  - Follow-up in 30 days.

---

**WFH/L** is Weight-for-Height or Weight-for-Length determined by using the WHO growth standards charts.

**MUAC** is Mid-Upper Arm Circumference measured using MUAC tape in all children 6 months or older.

**RUTF** is Ready-to-Use Therapeutic Food for conducting the appetite test and feeding children with severe acute malnutrition.

---

"[°] WFH/L is Weight-for-Height or Weight-for-Length determined by using the WHO growth standards charts.

**MUAC** is Mid-Upper Arm Circumference measured using MUAC tape in all children 6 months or older.

**RUTF** is Ready-to-Use Therapeutic Food for conducting the appetite test and feeding children with severe acute malnutrition."
PREVENTIVE MEDICINE IN OBSTETRICS, PAEDIATRICS AND GERIATRICS

Then Check for Anaemia

Check for anaemia
- Look for palmar pallor
  - Severe: pink +
  - Some: pink
- Assess mouth, gums
  - Severe: yellow
  - Some: yellow

* Assess the mouth closely, if the gums are receded
** If child has severe acute respiratory and measles RTI, PNDT give iron because severe iron deficit is not always severe RTI

- Give iron**
  - Ensure to follow the in-feeding, and continue for 6 weeks
  - Give vitamin A 200,000 IU at 6 months
  - Give vitamin A 200,000 IU at 9 months

Then Check the Child's Immunization*, Prophylactic Vitamin A & Iron-Folic Acid Supplementation Status

Immunization Schedule:
Please refer to page 142 for national immunization schedule

Prophylactic Vitamin A
- Give a single dose of vitamin A:
  - 100,000 IU at 9 months with measles immunization
  - 200,000 IU at 16-18 months with DPT Booster
  - 200,000 IU at 24 months
  - 200,000 IU at 30 months
  - 200,000 IU at 36 months

Prophylactic IFA
- Give 2mg iron and 50 micrograms folic acid (IFA)
- Give vitamin A at 9 months and 6 months
- Give vitamin A at 6 months

* A child who needs to be immunized should be allowed to go for immunization the day he was seen at the clinic

Assess Other Problems

Make sure child with any general danger sign is referred after first dose of an appropriate antibiotic and other urgent treatment.

Exception: Rehydration of the child according to Plan C may resolve danger signs so that referral is no longer needed.
### GIVE EXTRA FLUID FOR DIARRHOEA AND CONTINUE FEEDING

**PLAN A: TREAT DIARRHOEA AT HOME**

Counsel the mother on the 4 rules of home treatment:

1. **Give extra fluid:**
   - Breastfeed frequently and for longer at each feed.
   - If the child is exclusively breastfed, give ORS or clean water in addition to breast milk.
   - If the child is not exclusively breastfed, give one or more of the following:
     - ORS solution, fruit-based fluids (such as soup, rice water, and yoghurt drinks), or clean water.

2. **Give zinc supplements (age 2 months up to 5 years):**
   - Infants - dissolve tablet in a small amount of expressed breast milk, ORS or clean water in a cup.
   - Older children - tablets can be chewed or dissolved in a small amount of water.

3. **Continue feeding:**
   - Exclusive breastfeeding if age less than 6 months.

4. **When to return:**
   - If the child has been treated with Plan B or Plan C during this visit.
   - The child cannot return to a clinic if the diarrhoea gets worse.

**1. GIVE EXTRA FLUID (as much as the child will take)**

- Tell the mother:
  - Breastfeed frequently and for longer at each feed.
  - If the child is exclusively breastfed, give ORS or clean water in addition to breast milk.
  - If the child is not exclusively breastfed, give one or more of the following:
    - ORS solution, fruit-based fluids (such as soup, rice water, and yoghurt drinks), or clean water.

- It is especially important to give ORS at home when:
  - the child has been treated with Plan B or Plan C during this visit.
  - the child cannot return to a clinic if the diarrhoea gets worse.

- Teach the mother how to mix and give ORS. Give the mother 2 packets of ORS to use at home.

- Show the mother how much fluid to give in addition to the usual fluid intake:

<table>
<thead>
<tr>
<th>Age</th>
<th>Amount after each loose stool</th>
</tr>
</thead>
<tbody>
<tr>
<td>Under 2 12 months</td>
<td>50 to 100 ml</td>
</tr>
<tr>
<td>2 years or more</td>
<td>100 to 200 ml</td>
</tr>
</tbody>
</table>

- Tell the mother to:
  - Give frequent small sips from a cup.
  - If the child vomits, wait 10 minutes. Then continue, but more slowly.
  - Continue giving extra fluid until the diarrhoea stops.

**2. GIVE ZINC (age 2 months up to 5 years)**

- Tell the mother how much zinc to give (20 mg tab):

<table>
<thead>
<tr>
<th>Age</th>
<th>Amount daily for 14 days</th>
</tr>
</thead>
<tbody>
<tr>
<td>2 months up to 6 months</td>
<td>½ tablet daily</td>
</tr>
<tr>
<td>6 months or more</td>
<td>1 tablet daily</td>
</tr>
</tbody>
</table>

- Show the mother how to give zinc supplements:
  - Infants - dissolve tablet in a small amount of expressed breast milk, ORS or clean water in a cup.
  - Older children - tablets can be chewed or dissolved in a small amount of water.

**3. CONTINUE FEEDING**

- Exclusive breastfeeding if age less than 6 months.

**4. WHEN TO RETURN**

---

**PLAN B: TREAT SOME DEHYDRATION WITH ORS**

In the clinic, give recommended amount of ORS over 4-hours period:

- Determine amount of ORS to give during first 4 hours:

<table>
<thead>
<tr>
<th>WEIGHT</th>
<th>0-&lt;6 kg</th>
<th>6-&lt;10 kg</th>
<th>10-&lt;12 kg</th>
<th>12-19 kg</th>
</tr>
</thead>
<tbody>
<tr>
<td>AGE</td>
<td>Up to 4 months</td>
<td>4 months up to 12 months</td>
<td>12 months up to 2 years</td>
<td>2 years up to 5 years</td>
</tr>
<tr>
<td>0</td>
<td>200-450</td>
<td>450-800</td>
<td>800-960</td>
<td>960-1600</td>
</tr>
</tbody>
</table>

- Use the child's age only when you do not know the weight. The approximate amount of ORS required in ml can also be calculated by multiplying the child's weight (in kg) times 75.

- If the child needs more ORS than shown, give more.

- Infants or 0-6 months not breastfed also give 100-200 ml clean water during this period even if using standard ORS. This is not needed if you use new low osmolarity ORS.

- Show the mother how to give ORS solution:
  - Give frequent small sips from a cup.
  - If the child vomits, wait 10 minutes. Then continue, but more slowly.
  - Continue breastfeeding whenever the child wants.

- After 4 hours:
  - Reassess the child and classify the child for dehydration.
  - Select the appropriate plan to continue treatment.
  - Begin feeding the child in clinic.

- If the mother must leave before completing treatment:
  - Show her how to prepare ORS solution at home.
  - Show her how much ORS to give to finish 4-hours treatment at home.
  - Give her enough ORS packets to complete rehydration. Also give her 2 packets as recommended in Plan A.
  - Explain the 4 Rules of Home Treatment:
    1. GIVE EXTRA FLUID:
    2. GIVE ZINC (age 2 months up to 5 years).
    3. CONTINUE FEEDING (exclusive breastfeeding if age less than 6 months); and
    4. WHEN TO RETURN.
GIVE EXTRA FLUID FOR DIARRHOEA AND CONTINUE FEEDING

PLAN C: TREAT Severe Dehydration QUICKLY

Follow the arrows. If answer is "YES", go across. If "NO", go down.

START HERE

Can you give intravenous (IV) fluid immediately?

YES

NO

- Start IV fluid Immediately. If the child can drink, give ORS by mouth while the drip is set up. Give 100 ml kg Ringer's Lactate Solution (or, if not available, normal saline), divided as follows:

<table>
<thead>
<tr>
<th>Age</th>
<th>First give 30 ml/kg in:</th>
<th>Then give 70 ml/kg in:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Infants (under 12 months)</td>
<td>1 hour *</td>
<td>5 hours</td>
</tr>
<tr>
<td>Children (12 months up to 5 years)</td>
<td>30 minutes *</td>
<td>2 hours</td>
</tr>
</tbody>
</table>

- Repeat once if radial pulse is still very weak or not detectable
- Re-assess the child every 1-2 hours. If hydration status is not improving, give the IV drip more rapidly.
- Also give ORS (about 5 ml/kg/hour) as soon as the child can drink: usually after 3-4 hours (infants) or 1-2 hours (children)
- Re-assess an infant after 6 hours and a child after 3 hours. Classify dehydration. Then choose the appropriate plan (A, B or C) to continue treatment.

If IV treatment available nearby (within 30 minutes)?

YES

NO

- Refer URGENTLY to the hospital for IV treatment.
- Give the child curd mixer; provide the mother with ORS solution and show her how to give frequent sips during the trip or give ORS by naso-gastric tube.

Are you trained to use a naso-gastric tube for rehydration?

YES

NO

- Start rehydration by tube (or mouth) with ORS solution: give 20 ml/kg for 6 hours (total of 120 ml/kg)
- Re-assess the child every 1-2 hours while waiting for transfer:
  - If there is repeated vomiting or increasing abdominal distension, give the fluid more slowly.
  - If hydration status is not improving after 3 hours, send the child for IV therapy.
- After 6 hours, reassess the child. Classify dehydration. Then choose the appropriate plan (A, B or C) to continue treatment.

Can the child drink?

YES

NO

- Refer URGENTLY to the hospital for IV or NO treatment.

NOTE:
- If the child is not referred to hospital, observe the child at least 6 hours after rehydration to be sure the mother can maintain hydration giving the child ORS solution by mouth.

Nutrition may be defined as the science of food and its relationship to health. It is concerned primarily with the part played by nutrients in body growth, development and maintenance (1). The word Nutrient or "food factor" is used for specific dietary constituents such as proteins, vitamins and minerals. Dietetics is the practical application of the principles of nutrition; it includes the planning of meals for the well and the sick. Good nutrition means "maintaining a nutritional status that enables us to grow well and enjoy good health" (2). The subject of nutrition is very extensive. Since our concern is with community aspects of nutrition, the subject will be dealt with in five sections: dietary constituents, nutritional requirements, assessment of nutritional status, nutritional problems in public health and nutritional programmes in India.

Changing concepts

Through centuries, food has been recognized as important for human beings, in health and disease. The history of mankind has been a struggle to obtain food. Until the turn of the nineteenth century the science of nutrition had a limited range. Protein, carbohydrate and fat had been recognized early in the 19th century as energy-yielding foods and much attention was paid to their metabolism and contribution to energy requirements (3). The discovery of vitamins "rediscovered" the science of nutrition. Between the two World Wars, research on protein gained momentum. By about 1950, all the presently known vitamins and essential amino acids had been discovered. Nutrition gained recognition as a scientific discipline, with roots in physiology and biochemistry. In fact nutrition was regarded as a branch of physiology and taught as such to medical students. Great advances have been made during the past 50 years in knowledge of nutrition and in the practical application of that knowledge. Specific nutritional diseases were identified and technologies developed to control them, as for example, protein energy malnutrition, endemic goitre, nutritional anaemia, nutritional blindness and diarrhoeal diseases.

While attention was concentrated on nutritional deficiency diseases during the first decades of the century, the science of nutrition was extending its influence into other fields — agriculture, animal husbandry, economics and sociology. This led to "green revolution" and "white revolution" in India and increased food production. However, studies of the diets and state of nutrition of people in India showed that poorer sections of the population continued to suffer from malnutrition despite increased food production. One result was that for the first time the problem of nutrition began to attract international attention (3) as a cause of social problems. International activities in the field of nutrition initiated by the League of Nations, later continued by FAO, WHO and UNICEF form a striking part of the story.

Significant advances have been made during the past two decades. The association of nutrition with infection, immunity, fertility, maternal and child health and family health have engaged scientific attention. More recently, a great deal of interest has been focussed on the role of dietary factors in the pathogenesis of non-communicable diseases such as coronary heart disease, diabetes and cancer.

It has been said that most nutrition scientists are far more familiar with rats than with humans. Of greater significance during recent years is that the science of nutrition has moved out of the laboratory and linked itself to epidemiology. This association has given birth to newer concepts in nutrition such as epidemiological assessment of nutritional status of communities, nutritional and dietary surveys, nutritional surveillance, nutritional and growth monitoring, nutritional rehabilitation, nutritional indicators and nutritional interventions — all parts of what is broadly known as nutritional epidemiology. Epidemiological methods are now increasingly used not only in the elucidation of disease aetiology and identification of risk factors of disease, but also in the planning and evaluation of nutritional programmes. With these newer concepts and newer approaches, nutritional science has become more dynamic.

Another concept that has emerged in recent years is that nutrition is the cornerstone of socio-economic development, and that nutritional problems are not just medical problems but are "multifactorial" with roots in many other sectors of development such as education, demography, agriculture and rural development. It has become apparent that lasting improvement in the health and nutritional status of people can be brought about only through a successful attack on the basic problems of poverty and injustice. The old concept that the health sector alone is responsible for all nutritional ills of the community has faded away. It is now realized that a broad intersectoral and integrated approach of sectors of development is needed to tackle today's nutritional problems.

In the global campaign of Health for All, promotion of proper nutrition is one of the eight elements of primary health care (4). Nutritional indicators (5) have been developed to monitor "Health for All". Greater emphasis is now placed on integrating nutrition into primary health care systems whenever possible, and formulation of national dietary goals to promote health and nutritional status of families and communities.
CLASSIFICATION OF FOODS

There are many ways of classifying foods:

1. Classification by origin:
   1) Foods of animal origin
   2) Foods of vegetable origin.

2. Classification by chemical composition:
   1) Proteins
   2) Fats
   3) Carbohydrates
   4) Vitamins
   5) Minerals

3. Classification by predominant function:
   1) Body-building foods, e.g., milk, meat, poultry, fish, eggs, pulses, nuts, and oil seeds etc.
   2) Energy-giving foods, e.g., cereals, sugars, roots and tubers, fats and oils
   3) Protective foods, e.g., vegetables, fruits, milk.

4. Classification by nutritive value:
   1) Cereals and millets
   2) Pulses (legumes)
   3) Vegetables
   4) Nuts and oilseeds
   5) Fruits
   6) Animal foods
   7) Fats and oils
   8) Sugar and jaggery
   9) Condiments and spices
   10) Miscellaneous foods

NUTRIENTS

Nutrients are organic and inorganic complexes contained in food. There are about 50 different nutrients which are normally supplied through the foods we eat. Each nutrient has specific functions in the body. Most natural foods contain more than one nutrient. These may be divided into:

(i) Macronutrients: These are proteins, fats and carbohydrates which are often called "proximate principles" because they form the main bulk of food. In the Indian dietary, they contribute to the total energy intake in the following proportions:

<table>
<thead>
<tr>
<th>Nutrient</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Proteins</td>
<td>10 to 15 per cent</td>
</tr>
<tr>
<td>Fats</td>
<td>15 to 30 per cent</td>
</tr>
<tr>
<td>Carbohydrates</td>
<td>50 to 80 per cent</td>
</tr>
</tbody>
</table>

(ii) Micronutrients: These are vitamins and minerals. They are called micronutrients because they are required in small amounts which may vary from a fraction of a milligram to several grams. A short review of basic facts about these nutrients is given below.

PROTEINS

The word "protein" by derivation means that which is of first importance. Indeed they are of the greatest importance in human nutrition. Proteins are complex organic nitrogenous compounds. They are composed of carbon, hydrogen, oxygen, nitrogen and sulphur in varying amounts. Some proteins also contain phosphorus and iron and occasionally other elements. Proteins differ from carbohydrates and fats in that they contain nitrogen, this usually amounts to about 16 per cent. Proteins constitute about 20 per cent of the body weight in an adult.

Essential amino acids

Proteins are made up of smaller units, called amino acids. Some 20 amino acids are stated to be needed by the human body, of which 9 are called "essential" because the body cannot synthesize them in amounts corresponding to its needs, and therefore, they must be obtained from dietary proteins. They are: leucine, isoleucine, lysine, methionine, phenylalanine, threonine, valine, tryptophan and histidine. Evidence is now accumulating that histidine is essential even for adults. Non-essential amino acids include arginine, asparaginic acid, serine, glutamic acid, proline and glycine. Both essential and non-essential amino acids are needed for synthesis of tissue proteins, the former must be supplied through diet, whereas the latter can be synthesized by the body provided other building blocks are present.

Some of the essential amino acids have important biological functions, e.g., formation of niacin from tryptophan; the action of methionine as a donor of methyl groups for the synthesis of choline, folates and nucleic acids. There is evidence that cystine and tyrosine are essential for premature babies. New tissues cannot be formed unless all the essential amino acids (EAA) are present in the diet.

A protein is said to be "biologically complete" if it contains all the EAA in amounts corresponding to human needs. When one or more of the EAA are lacking, the protein is said to be "biologically incomplete". The quality of dietary protein is closely related to its pattern of amino acids. From the nutritional standpoint, animal proteins are rated superior to vegetable proteins because they are "biologically complete". For example milk and egg proteins have a pattern of amino acids considered most suitable for humans.

Functions

Proteins are needed by the body for (a) body building; this component is small compared with the maintenance component, except in the very young child and infant; (b) repair and maintenance of body tissues; (c) maintenance of osmotic pressure; and (d) synthesis of certain substances like antibodies, plasma proteins, haemoglobin, enzymes, hormones and coagulation factors. Proteins are connected with the immune mechanism of the body. The cell mediated immune response and the bactericidal activity of leucocyte have been found to be lowered in severe forms of protein energy malnutrition. Proteins can also supply energy (4 kcal per one gram) when the calorie intake is inadequate, but this is not their primary function. It is considered wasteful if proteins were used for such a purpose.

Sources

Humans obtain protein from two main dietary sources: (a) ANIMAL SOURCES: Proteins of animal origin are found in milk, meat, eggs, cheese, fish and fowl. These proteins contain all the essential amino acids (EAA) in adequate amounts. Egg proteins are considered to be the best among food proteins because of their high biological value and digestibility. They are used in nutrition studies as a "reference protein". (b) VEGETABLE SOURCES: Vegetable proteins are found in pulses (legumes), cereals, beans, nuts, oil-seed cakes, etc. They are poor in EAA. In developing countries such as India, cereals and pulses are the main sources of dietary protein because they are cheap, easily available and consumed in bulk. Protein content of some foods are as given in Table 1.
Supplementary action of proteins

Man derives protein not from a single source, but from a variety of food sources, animal and vegetable. Cereal proteins are deficient in lysine and threonine; and pulse proteins in methionine. These are known as "limiting" amino acids. When two or more of vegetarian foods are eaten together (as for example, rice-dhal combination in amino acids. When two or more of vegetarian foods are proteins in methionine. These are known as "limiting" proteins are deficient in lysine and threonine; and pulse variety of food sources, animal and vegetable. Cereal supplementary action of proteins that is retained in the body under specified conditions for biological value and digestibility coefficient divided by protein utilization (8). The net protein utilization (NPU) is also required about the digestibility and suitability to meet the protein needs of the body. The parameters used for such an evaluation include the estimation of the biological value, digestibility coefficient, protein efficiency ratio and net protein utilization (8). The net protein utilization (NPU) is considered of more practical value because it is the product of biological value and digestibility coefficient divided by 100. In exact terms, it is the "proportion of ingested protein that is retained in the body under specified conditions for the maintenance and/or growth of the tissues". In other words, growth is an important yardstick for ascertaining the essentiality of a nutrient.

Assessment of protein nutrition status

A battery of tests have been suggested to assess the state of protein nutrition. These include : arm muscle circumference, the creatinine – height index, serum albumin and transferrin, total body nitrogen, etc.

At the present time the best measure of the state of protein nutrition is probably serum albumin concentration. It should be more than 3.5 g/dl, a level of 3.5 g/dl is considered mild degree of malnutrition; a level of 3.0 g/dl severe malnutrition. Serum albumin and transferrin assess the ability of the liver to synthesize proteins.

Protein requirements

It is customary to express protein requirements in terms of body weight. The Indian Council of Medical Research in 2010 (9) recommended 1.0 g protein/kg body weight for an Indian adult, assuming a NPU of 65 for the dietary proteins. Daily allowances recommended by the ICMR for various population groups are as given in Table 29.

FATS

Fats are solid at 20 deg. C; they are called "oils" if they are liquid at that temperature. Fats and oils are concentrated sources of energy. They are classified as :

(a) Simple lipids, e.g., triglycerides
(b) Compound lipids, e.g., phospholipids
(c) Derived lipids, e.g., cholesterol

The human body can synthesize triglycerides and cholesterol endogenously. Most of the body fat (99 per cent) in the adipose tissue is in the form of triglycerides. In normal human subjects, adipose tissue constitutes between 10 to 15 per cent of body weight. The accumulation of one kilogram of adipose tissue corresponds to 7,700 kcal of energy (10).

Fatty acids

Fats yield fatty acids and glycerol on hydrolysis. Fatty acids are divided into saturated fatty acids such as lauric, palmitic and stearic acids, and unsaturated fatty acids which are further divided into monounsaturated (MUFA) (e.g., oleic acid) and poly-unsaturated fatty acids (PUFA) (e.g., linoleic acid and α-linolenic acid). Table 2 shows the fatty acid content of different fats.

The poly-unsaturated fatty acids are mostly found in vegetable oils, and the saturated fatty acids mainly in animal fats. However, there are exceptions, as for example, coconut and palm oils, although vegetable oils, have an extremely high percentage of saturated fatty acids. On the other hand, fish oils, although they are not vegetable oils, contain poly and mono-unsaturated fatty acids.

Essential fatty acids

Essential fatty acids are those that cannot be synthesized by humans. They can be derived only from food. The most important essential fatty acid (EFA) is linoleic acid, which serves as a basis for the production of other essential fatty acids (e.g., linolenic and arachidonic acids). Not all polyunsaturated fatty acids are essential fatty acids.

Source : (11)

Sources

The dietary sources of fats may be classified as :

(a) ANIMAL FATS : The major sources of animal fats are ghee, butter, milk, cheese, eggs, and fat of meat and fish.

Animal fats with few exceptions like cod liver oil and sardine oil are mostly saturated fats.

(b) VEGETABLE FATS : Some plants store fat in their seeds, e.g., groundnut, mustard, sesame, coconut, etc. They are sources of vegetable oils.

(c) OTHER SOURCES : Small quantities of fat (invisible fat) are found in most other foods such as cereals, pulses, nuts and vegetables. For example, rice carries 3 per cent of fat, wheat 3 per cent, jowar 4 per cent and bajra 6.5 per cent. Large cereal consumption, as in India, provides considerable amounts of “invisible fat”. Moreover, the body can convert carbohydrate into fat.

Visible and invisible fats

“Visible” fats are those that are separated from their natural source, e.g., ghee (butter) from milk, cooking oils from oil-bearing seeds and nuts. It is easy to estimate their intake in the daily diet. “Invisible” fats are those which are not visible to the naked eye. They are present in almost every article of food, e.g., cereals, pulses, nuts, milk, eggs, etc. It is difficult to estimate their intake. In fact, the major contribution to total fat intake is from invisible sources rather than visible sources as cereals and pulses constitute the bulk of Indian diet.

Edible plant foods have a low content of fat and saturated fatty acids but they are good source of mono-unsaturated fatty acids and poly-unsaturated fatty acids. In most cereals, millets, pulses and legumes, fat content ranges between 1.5 to 3 per cent. In cereals, millets and most oil seeds, linoleic acid is the major fatty acid whereas pulses, legumes, green leafy vegetables and some oil seeds (e.g. soya bean, rapeseed/mustard and flaxseed) and fenugreek are good sources of both linoleic acid and alpha-linolenic acid. Animal foods like butter, ghee, whole milk cream, fatty cheese and fatty meats provide cholesterol and high amount of saturated fatty acids, and are natural source of trans-fatty acids. Lean meats have a fairly high content of long chain poly-unsaturated fatty acids (PUFA). Edible plant meats contains less fat and cholesterol and have high amount of PUFA including long chain PUFA. Edible plant meats contain less fat and cholesterol and have high amount of PUFA including long chain PUFA. Edible plant meats contain less fat and cholesterol and have high amount of PUFA including long chain PUFA. Edible plant meats contain less fat and cholesterol and have high amount of PUFA including long chain PUFA. Edible plant meats contain less fat and cholesterol and have high amount of PUFA including long chain PUFA. Edible plant meats contain less fat and cholesterol and have high amount of PUFA including long chain PUFA.

The total quantity of invisible fat and its fatty acid composition depends on the kind of diet consumed (9).

Vegetable oil used in cooking is the major type of visible fat consumed; vanaspati and ghee are the other sources. India has a wide range of edible vegetable oils (groundnut, rapeseed/mustard, soya bean, sunflower, sesame, safflower, rice bran, cottonseed and linseed). In India, the type of vegetable oil consumed varies from one part of the country to the other. Vanaspati (PHVO) promoted as vegetable ghee is used as a substitute for ghee and is used in preparing commercially fried, processed, ready to eat, packaged, frozen, pre-mixed foods and street foods. In recent years, there is change in choice of cooking oils in the urban population. The daily intake of visible fat in rural India is about the same as reported about 25 years back (9).

Functions

Fats have always been equated with calories. They are high energy foods, providing as much as 9 kcal for every gram. By supplying energy, fats spare proteins from being used for energy. Besides providing energy, fats serve as...
vehicles for fat-soluble vitamins. Fats in the body support viscera such as heart, kidney and intestine; and fat beneath the skin provides insulation against cold. Without fat, food is limited in palatability.

It is only recently that the "non-calorie" roles of fats have been discovered. For example vegetable fats are rich sources of essential fatty acids which are needed by the body for growth, for structural integrity of the cell membrane and decreased platelet adhesiveness. Diets rich in EFA have been reported to reduce serum cholesterol and low-density lipoproteins (12). Poly-unsaturated fatty acids are precursors of prostaglandin – a group of compounds, now recognized as "local hormones"; they play a major role in controlling many of the physiological functions of the body such as vascular haemostasis, kidney function, acid secretion in stomach, gastro-intestinal motility, lung physiology and reproduction. Cholesterol is essential as a component of membranes and nervous tissue and is a precursor for the synthesis of steroid hormones and bile acids. Thus fats and oils are useful to the body in several ways.

Hydrogenation

When vegetable oils are hydrogenated under conditions of optimum temperature and pressure in the presence of a catalyst, the liquid oils are converted into semi-solid and solid fat. The resulting hydrogenated fat is known as "vanaspati" or vegetable ghee, which is a popular cooking medium in India.

During the process of hydrogenation, unsaturated fatty acids are converted into saturated acids and the EFA content is drastically reduced. The main advantage of vanaspati is its ghee-like consistency and its keeping quality even in hot humid climates. Since vanaspati is lacking in fat-soluble vitamins, it is fortified with vitamins A and D by government regulation to the extent of 2500 IU of vitamin A and 175 IU of vitamin D per 100 grams.

Trans-fatty acids

Trans-fatty acids are geometrical isomers of Cis-unsaturated fatty acids that adapt a saturated fatty acid like configuration. Partial hydrogenation, the process used to increase shelf-life of poly-unsaturated fatty acids (PUFAs) create trans fatty acids and also removes the critical double bonds in essential fatty acids. Metabolic studies have demonstrated that trans-fatty acids render the plasma lipid profile even more atherogenic than saturated fatty acids, by not only elevating LDL cholesterol but also by decreasing HDL cholesterol. Several large cohort studies have found that intake of trans-fatty acids increases the risk of coronary heart disease (13). It takes years for trans fatty acids to be flushed from the body. Deep fried fast foods, cake mixes, cereals and energy bars, chips and crackers and whipped toppings, packaged cookies and candy, packaged doughnuts, pies and cakes are major sources of trans-fatty acids. It is better to look for "partially hydrogenated oil" on the label of any packaged food.

Refined oils

Refining is usually done by treatment with steam, alkali, etc. Refining and deodorization of raw oils is done mainly to remove the free fatty acids and rancid materials which may be present in them. Refining does not bring about any change in the unsaturated fatty acid content of the oil. It only improves the quality and taste of oils. Refined oils are costly.

Fats and disease

(a) OBESITY: A diet, rich in fat, can pose a threat to human health by encouraging obesity. In fat people, adipose tissue may increase upto 30 per cent. (b) PHRENODERMA: Deficiency of essential fatty acids in the diet is associated with rough and dry skin, a condition known as phrenoderma or "toad skin". This condition is reported in Kerala, Karnataka and Gujarat (14). It is characterized by horny papular eruptions on the posterior and lateral aspects of limbs and on the back and buttocks. Phrenoderma can be cured rapidly by the administration of linseed or safflower oil which are rich in EFA, along with vitamins of the B-complex group. (c) CORONARY HEART DISEASE: High fat intake (i.e., dietary fat representing 40 per cent or over of the energy supply and containing a high proportion of saturated fats) has been identified as a major risk factor for CHD (15). Epidemiological studies indicate that LDL and VLDL fractions are atherogenic and HDL exerts a protective effect against the development of atherosclerosis. There is evidence indicating an inverse relationship between EFA intake and CHD mortality. (d) CANCER: In recent years, there has been some evidence that diets high in fat increase the risk of colon cancer and breast cancer (16). (e) OTHERS: The skin lesions of kwashiorkor and those induced by EFA deficiency are similar. The possible association between the skin lesions of kwashiorkor and EFA deficiency has attracted attention (18).

The WHO/FAO Expert Group on diet, nutrition and prevention of chronic diseases endorse that qualitative composition of fats in the diet has a significant role to play in modifying risk factors of CVD and set the following ranges for population nutrient goals (% of Energy) : total fat, 15-30 (at least 20% of energy) is consistent with good health; Saturated fatty acids less than 10 per cent; PUFAs 6-10 per cent; n-6 about 5-8 per cent; n-3 about 1-2 per cent; Trans-fatty acids less than 1 per cent; MUFAs by difference, and cholesterol less than 300 mg a day (9).

The FAO-WHO expert consultation on fats and fatty acids in human nutrition held in November 2008 in Geneva, Switzerland, reviewed the scientific evidence on nutrient intake values for total fat and fatty acids for different life stages. It also assessed the risks to adequate growth, development and maintenance of health and provided recommendations for infants, children, adults and for women during pregnancy and lactation. Some of their conclusions and recommendations are as follows:

(a) There is convincing evidence on the following:

Energy balance is critical to maintain healthy body weight and ensure optimal nutrient intakes, regardless of macronutrient distribution of energy as % total fat and % total carbohydrates.

Saturated fatty acids (SFAs):

(1) Replacing SFAs with PUFAs decreases LDL cholesterol concentration and the total HDL cholesterol ratio. A similar but lesser effect is achieved by replacing these SFAs with MUFAs.

(2) Replacing SFAs with carbohydrates decreases both LDL and HDL cholesterol concentration but does not change the total/HDL cholesterol ratio.

(3) Replacing SFAs with trans-fatty acids (TFAs) decreases HDL cholesterol and increases the total/HDL cholesterol ratio.

(4) Considering the data from epidemiological studies on
morbidity and mortality due to coronary heart disease (CHD) and controlled clinical trials (using CHD events and death), it was also agreed that replacing SFAs with PUFAs decrease the risk of CHD.

**MUFAs (Monounsaturated fatty acids)**

1. Replacing carbohydrates with MUFAs increases HDL cholesterol concentrations.
2. Replacing SFA with MUFA reduces LDL cholesterol concentration and total HDL cholesterol ratio.

**PUFAs (Polyunsaturated fatty acids)**

- Linoleic acid (LA) and alpha-linolenic acid (ALA) are indispensable since they cannot be synthesized by humans. Minimum intake levels for essential fatty acids to prevent deficiency symptoms are estimated to be 2.5% E LA plus 0.5% E ALA.

**Trans-fatty acids (TFAs)**

TFAs from commercial partially hydrogenated vegetable oils (PHVO) increase CHD risk factors and CHD events to a greater extent than what was thought earlier.

**Fat requirements**

Recommendations for dietary fats for Indians have been revised taking into account the recent FAO and WHO recommendations for: (1) total fat, individual fatty acids and health promoting non-glycemic components; (2) source of dietary fats in Indians; and (3) availability of fat. The recommendations are directed towards meeting the requirements of optimal foetal and infant growth and development, maternal health and for combating chronic energy deficiency in children and adults, and diet related non-communicable diseases in adults.

Taking into account the unfavourable effect of low-fat high-carbohydrate diets and the energy requirement set on the basis of age, physiological status and physical activity, the minimum intake of visible fat for Indian adults range between 20-40 g/day. The minimum level of total fat should be 20 per cent of energy. To furnish 20 per cent of total energy, diet of pregnant and lactating mothers should contain at least 30 grams of visible fat (9). For further details see Table 28.

**CARBOHYDRATES**

The third major component of food is carbohydrate, which is the main source of energy, providing 4 kcals per gram. Carbohydrate is also essential for the oxidation of fats and for the synthesis of certain non-essential amino acids. There are three main sources of carbohydrates, viz., starches, sugar and cellulose. Starch is basic to the human diet. It is found in abundance in cereals, roots and tubers. Sugars comprise monosaccharides (glucose, fructose and galactose) and disaccharides (sucrose, lactose and maltose). These free sugars are highly water soluble and easily assimilated. Free sugars along with starches constitute a key component of dietary fibre which is the indigestible component of carbohydrate with scarcely any nutritive value, contributes to dietary fibre.

The carbohydrate reserve (glycogen) of a human adult is about 500 g. This reserve is rapidly exhausted when a man is fasting. If the dietary carbohydrates do not meet the energy needs of the body, protein and glyceral from dietary and endogenous sources are used by the body to maintain glucose haemostasis.

**Glycaemic index (9)**

Glycaemic index of a food is defined by the area under the two-hour blood glucose response curve (AUC) following the ingestion of a fixed portion of test carbohydrate (usually 50 g) as a proportion (%) of the AUC of the standard (either glucose or white bread).

Some foods containing different fractions of soluble and
insoluble fibres favour slow release of sugar into small intestine and its absorption into blood (reduced peak and prolonged rate). They are therefore termed low glycaemic index foods as compared to high glycaemic foods with readily digestible and absorbable sugar. The concept has practical utility in management of diabetes and control of obesity. The classification of foods according to GI is as follows:

<table>
<thead>
<tr>
<th>Classification</th>
<th>GI range</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>Low GI</td>
<td>55 or less</td>

</tr>
<tr>
<td>High GI</td>
<td>70 or more</td>
<td>corn flakes, baked potato, some white rice varieties (e.g. jasmine), white bread, candy bar and surupiy foods</td>
</tr>
</tbody>
</table>

DIETARY FIBRE

By definition "Dietary fibre is the remnants of the edible part of plants and analogous carbohydrates that are resistant to digestion and absorption in the human small intestine with complete or partial fermentation in the human large intestine". It includes polysaccharides, oligosaccharides, lignin and associated plant substances. Dietary fibre exhibits one or more of either laxation (faecal bulking and softening; increased frequency; and or regularity), blood cholesterol attenuation, and or blood glucose attenuation. Organic acids (butyric acid) and polyols (sorbitol) are also considered as part of fibre. Animal foods do not contain any fibre.

Type and sources

Dietary fibres have been characterized by its source, e.g., cereal, vegetable and fruits or its solubility in water - soluble (partly or fully) or insoluble. Both characters of solubility are essential for health promotion. Digestibility of fibre is determined by physiochemical and structural properties of the dietary component and the process used. When exposed to longer duration of degradative conditions in large intestine, more fibre is digested. It forms the substance for fermentation by intestinal microbes. It is through this mechanism that part of energy from resistant starch is rendered available. Apart from the energy yielding reactions during digestion, at different pH, the action of enzymes on dietary fibres promotes interaction between nutrients. It also changes the pattern of microbes colonizing the colon and thus the metabolic products of such fermentation over the time. Vegetarians may have different digestion pattern than that of the non-vegetarians and thus derive different health benefits. This knowledge of probiotics characterized by helpful microbes and prebiotics (substrates promoting the colonization of probiotic strains) has opened up new areas for research (9).

Different estimates of fibre covered all that was insoluble in boiling water or in dilute acid and alkali conditions. It was reported as 'crude fibre', which may include all structural fibre, cellulose, lignin and haem cellulose. It is related to digestibility and has the property of holding water and swelling properties of the diet. It adds to the bulk of the food, favours satiety, increases transit time of the food in the gut and is an active substrate in the large intestine for release of important functional components like organic acids and nutraceuticals. Mostly complex carbohydrates, such as polysaccharides i.e. cellulose, haem cellulose, pectin and a variety of gums, mucilages form the fibre.

Dietary fibre is known to be associated with reduced incidence of coronary heart disease. The mechanism of its action is attributed to its binding to bile salts and preventing its reabsorption and thus reducing cholesterol level in circulation. The fibre, particularly the gum and pectin, when ingested with a diet, are reported to reduce post-prandial glucose level in blood. Recent studies have shown that gum present in fenugreek seeds, which contains 40 per cent gum, is most effective in reducing blood glucose and cholesterol levels as compared to other gums.

Fibre have no metabolic effects. However, too much of fibre can decrease the absorption of valuable micronutrients. There is conflicting evidence as to whether fibre tends to bind some vitamins and minerals like calcium, magnesium, iron and zinc, and reduce their bio-availability. People who eat well-balanced diet obtain enough roughage. Considering the qualitative and quantitative decrease in fibre content of diet over the past many decades, an increase in dietary fibre, particularly from cereals emerge as a recommendation. Intake in excess of 60 g of fibre per day can reduce the nutrient absorption and cause bowel irritation (9). A daily intake of about 40 grams of dietary fibre per 2000 kcal is desirable. The actual quantity of fibre intake depends upon the nature of cereals, pulses, whole grain, vegetables and millets used. The total fibre content of common foods are as shown in Table 4

VITAMINS

Vitamins are a class of organic compounds categorized as essential nutrients. They are required by the body in very small amounts. They fall in the category of micronutrients. Vitamins do not yield energy but enable the body to use other nutrients. Since the body is generally unable to synthesize them (at least in sufficient amounts) they must be provided by food. A well-balanced diet supplies in most instances the vitamin needs of a healthy person.

Vitamins are divided into two groups: (a) fat-soluble vitamins, viz., vitamins A, D, E, and K; and (b) water-soluble vitamins, viz., vitamins of the B-group and vitamin C. Each vitamin has a specific function to perform and deficiency of any particular vitamin may lead to specific deficiency diseases. For some vitamins (e.g., vitamin E), no deficiency disease is yet known. The minimum intake for the maintenance of health in respect of many of the vitamins has been determined, but the optimum intake remains somewhat speculative.

VITAMIN A

"Vitamin A" covers both a pre-formed vitamin, retinol, and a pro-vitamin, beta-carotene, some of which is converted to retinol in the intestinal mucosa (17). The international units (IU) originally established for vitamin A and provitamin were discarded in 1954 and 1956 respectively (18). In 1960, the term "retinol" was introduced for vitamin A = 1 alcohol (which is available in crystalline form), but most workers prefer the older term vitamin A and the international unit (IU) of vitamin A is equivalent to 0.3 microgram of retinol (or 0.55 microgram of retinol palmitate).

Some food composition tables give separate values for retinol and beta-carotene. To convert these into a single value, the term "retinol equivalent" (RE) has been conventionally adopted. The conversion can be done in the following way.

1 mcg of retinol = 1 RE
1 mcg of β-carotene = 0.167 mcg of RE
1 mcg of other carotenoids = 0.084 mcg of RE
1 RE = 3.333 IU of Vitamin A

Functions

Vitamin A participates in many bodily functions: (a) it is indispensable for normal vision. It contributes to the production of retinal pigments which are needed for vision in dim light. (b) it is necessary for maintaining the integrity and the normal functioning of glandular and epithelial tissue which lines intestinal, respiratory and urinary tracts as well as the skin and eyes. (c) it supports growth especially skeletal growth. (d) it is anti-infective; there is increased susceptibility to infection and lowered immune response in vitamin A deficiency, and (e) it may protect against some epithelial cancers such as bronchial cancers, but the data are not fully consistent (19). However, the role of vitamin A at the molecular level is not yet known.

Sources

Vitamin A is widely distributed in animal and plant foods - in animal foods as preformed vitamin A (retinol), and in plant foods as provitamins (carotenoids).

(a) ANIMAL FOODS: Foods rich in retinol are liver, eggs, butter, cheese, whole milk, fish and meat. Fish liver oils are the richest natural sources of retinol (Table 5), but they are generally used as nutritional supplements rather than as food sources.

(b) PLANT FOODS: The cheapest source of vitamin A is green leafy vegetables such as spinach and amaranth which are found in great abundance in nature throughout the year. The darker the green leaves, the higher its carotene content. Vitamin A also occurs in most green and yellow fruits and vegetables (e.g., papaya, mango, pumpkin) and in some roots (e.g., carrots). The most important carotenoid is beta-carotene which has the highest vitamin A activity. Carotenoids are converted to vitamin A in the small intestine. This action is poorly accomplished in malnourished children and those suffering from diarrhea.

(c) FORTIFIED FOODS: Foods fortified with vitamin A (e.g., vanaspati, margarine, milk) can be an important source. Vitamin A content of selected foods is as given in Table 5.

Source: (20)

The liver has an enormous capacity for storing vitamin A, mostly in the form of retinol palmitate. Under normal conditions, a well-fed person has sufficient vitamin A reserves to meet his needs for 6 to 9 months or more. Free retinol is highly active but toxic and is therefore transported in the blood stream in combination with retinol-binding protein, which is produced by the liver. In severe protein deficiency, decreased production of retinol-binding protein prevents mobilization of liver retinol reserves.

Deficiency

The signs of vitamin A deficiency are predominantly ocular. They include nightblindness, conjunctival xerosis, Bitot's spots, corneal xerosis and keratomalacia. The term "xerophthalmia" (dry eye) comprises all the ocular manifestations of vitamin A deficiency ranging from nightblindness to keratomalacia. Given below is a short description of the ocular manifestations.

(a) Nightblindness

Lack of vitamin A, first causes nightblindness or inability to see in dim light. The mother herself can detect this condition when her child cannot see in late evenings or find her in a darkened room. Nightblindness is due to impairment in dark adaptation. Unless vitamin A intake is increased, the condition may get worse, especially when children also suffer from diarrhea and other infections.

(b) Conjunctival xerosis

This is the first clinical sign of vitamin A deficiency. The
VITAMINS 'are conjunctiva becomes dry and non-wettable. Instead of looking smooth and shiny, it appears muddy and wrinkled. It has been well described as “emerging like sand banks at receding tide” when the child ceases to cry (21).

(c) Bitot’s spots

Bitot’s spots are triangular, pearly-white or yellowish, foamy spots on the bulbar conjunctiva on either side of the cornea. They are frequently bilateral. Bitot’s spots in young children usually indicate vitamin A deficiency. In older individuals, these spots are often inactive sequelae of earlier disease.

(d) Corneal xerosis

This stage is particularly serious. The cornea appears dull, dry and non-wettable and eventually opaque. It does not have a moist appearance. In more severe deficiency there may be corneal ulceration. The ulcer may heal leaving a corneal scar which can affect vision.

(e) Keratomalacia

Keratomalacia or liquefaction of the cornea is a grave medical emergency. The cornea (a part or the whole) may become soft and may burst open. The process is a rapid one. If the eye collapses, vision is lost.

EXTRA-OCULAR MANIFESTATIONS

These comprise follicular hyperkeratosis, anorexia and growth retardation which have long been recognized. They are non-specific and difficult to quantify. Recent studies seem to indicate that even mild vitamin A deficiency causes an increase in morbidity and mortality due to respiratory and intestinal infection (22). Deficiency of vitamin A has recently been linked to child mortality (23).

Treatment

Vitamin A deficiency should be treated urgently. Nearly all of the early stages of xerophthalmia can be reversed by administration of a massive dose (200,000 IU or 110 mg of retinol palmitate) orally on two successive days (24). All children with corneal ulcers should receive vitamin A whether or not a deficiency is suspected.

Prevention

Prevention and/or control takes two forms – (a) improvement of people’s diet so as to ensure a regular and adequate intake of foods rich in vitamin A, and (b) reducing the frequency and severity of contributory factors, e.g., PEM, respiratory tract infections, diarrhoea and measles. Both are long term measures involving intensive nutrition education of the public and community participation.

Since vitamin A can be stored in the body for 6 to 9 months and liberated slowly, a short term, simple technology had been evolved by the National Institute of Nutrition at Hyderabad (India) for community based intervention against nutritional blindness, which has subsequently been adopted by other countries (25). The strategy is to administer a single massive dose of 200,000 IU of vitamin A in oil (retinol palmitate) orally every 6 months to preschool children (1 year to 6 years), and half that dose (100,000 IU) to children between 6 months and one year of age (24). In this way, the child would be, as it were “immunized” against xerophthalmia. The protection afforded by six-monthly dosing seems very adequate as measured by clinical signs of deficiency (26).

Assessment of vitamin A deficiency

The formulation of an effective intervention programme for prevention of vitamin A deficiency (VAD) begins with the characterization of the problem. This is done by population surveys employing both clinical and biochemical criteria. These surveys (prevalence surveys) are done on preschool children (6 months to 6 years) who are at special risk. The criteria recommended by WHO (18) are as given in Table 6. The presence of any one of the criteria should be considered as evidence of a xerophthalmia problem in the community.

Recommended allowances

The recommended daily intake of vitamin A is 600 micrograms for adults. The present expert committee has modified the extent of conversion efficiency from 1:4 to 1:8 and has retained the previous recommendation on retinol requirements for all age groups except pregnancy. The committee recommends that a minimum of 50 per cent retinol be drawn from animal sources (9). The detailed recommendations are as given in Table 7.

Source: (9)

Toxicity

An excess intake of retinol causes nausea, vomiting, anorexia and sleep disorders followed by skin desquamation and then an enlarged liver and papillary oedema. High
intakes of carotene may colour plasma and skin, but do not appear to be dangerous (19, 27). The teratogenic effects of massive doses of vitamin A is the most recent focus of interest (28).

**VITAMIN D**

The nutritionally important forms of Vitamin D in man are Calciferol (Vitamin D₃) and Cholecalciferol (Vitamin D₂). Calciferol may be derived by irradiation of the plant sterol, ergosterol. Cholecalciferol is the naturally occurring (preformed) vitamin D which is found in animal fats and fish liver oils. It is also derived from exposure to UV rays of the sunlight which convert the cholesterol in the skin to vitamin D. Vitamin D is stored largely in the fat depots.

**Vitamin D : Kidney hormone**

Major advances have been made in recent years in our understanding of the metabolism of vitamin D in the body (29). It is now known that vitamin D, by itself, is metabolically inactive unless it undergoes endogenous transformation into several active metabolites (e.g., 25 HCC; 1 : 25 DHCC) first in the liver and later in the kidney. These metabolites are bound to specific transport proteins and are carried to the target tissues — bone and intestine. It has been proposed that vitamin D should be regarded as a kidney hormone (30) because it does not meet the classic definition of a vitamin, that is, a substance which must be obtained by dietary means because of a lack of capacity in the human body to synthesize it. In fact, vitamin D₃ is not a dietary requirement at all in conditions of adequate sunlight. It can be synthesized in the body in adequate amounts by simple exposure to sunlight even for 5 minutes per day.

**Functions**

The functions of vitamin D are as summarized in Table 8.

**TABLE 8**

</tbody>
</table>

**Sources**

Vitamin D is unique because it is derived both from sunlight and foods. (a) **Sunlight** : Vitamin D is synthesized by the body by the action of UV rays of sunlight on 7-dehydrocholesterol, which is stored in large abundance in the skin. Exposure to UV rays is critical; these can be filtered off by air pollution. Dark-skinned races such as Negros, also suffer from this disadvantage because black skin can filter off up to 95 per cent of UV rays. (b) **Foods** : Vitamin D occurs only in foods of animal origin. Liver, egg yolk, butter and cheese, and some species of fish contain useful amounts. Fish liver oils, although not considered to be a food, are the richest source of vitamin D. Human milk has been shown to contain considerable amounts of water-soluble vitamin D sulphate (31). Other sources of vitamin D are foods artificially fortified with vitamin D, such as milk, margarine, vanaspati and infant foods. Dietary sources of vitamin D are as given in Table 9.

**Deficiency**

(1) **Rickets** : Vitamin D deficiency leads to rickets, which is usually observed in young children between the age of six months and two years. There is reduced calcification of growing bones. The disease is characterized by growth failure, bone deformity, muscular hypotonia, teta and convulsions due to hypocalcaemia. There is an elevated concentration of alkaline phosphate in the serum. The bony deformities include curved legs, deformed pelvis, pigeon chest, Harrison's sulcus, rickety rosary, kyphoscoliosis, etc. The milestones of development such as walking and teething are delayed. (2) **Osteomalacia** : In adults, vitamin D deficiency may result in osteomalacia which occurs mainly in women, especially during pregnancy and lactation when requirements of vitamin D are increased.

Both rickets and osteomalacia were frequently reported in India, although they do not appear to be a problem of public health importance. In the world as a whole, their prevalence has declined as a result of changes in social customs (e.g., purdah system), and the expansion of mother and child health services leading to better care and feeding of infants and children (3). In the developing countries today, rickets as a menace to child health is overshadowed by the prevalence of protein-energy-malnutrition.

**Prevention**

Prevention measures include (a) educating parents to expose their children regularly to sunshine; (b) periodic dosing (prophylaxis) of young children with vitamin D; and (c) vitamin D fortification of foods, especially milk. Some industrialized countries still carry out the last measure. Periodic dosing and education appear to be the most practical approaches in developing countries.

Fraser (32) urges caution concerning oral supplementation, because orally administered vitamin D appears to bypass the protective mechanism that prevent excessive 25(OH)D₃ formation. The margin of safety with oral vitamin D between the nutrient requirement and toxic intake is narrow.

Vitamin D is stored in the body in fatty tissues and in the liver. An excessive intake is harmful and may result in anorexia, nausea, vomiting, thirst, and drowsiness. The patient may lapse into coma, while cardiac arrhythmias and renal failure may occur. The effects are due to hypercalcaemia induced by increased intestinal absorption and mobilization of calcium from bone. Recent literature contains warning against the administration of amounts of vitamin D that greatly exceed accepted requirement levels. This warning applies to pregnant women also since manifestations of hypercalcaemia may develop in utero (4).

**Daily requirements**

The expert committee of ICMR emphasizes importance of outdoor physical activities as a means of achieving adequate vitamin D status in a tropical country like India. However,
under minimal exposure to sunlight, particularly in certain urban groups, like 1–2 year old children, a specific recommendation of a daily supplement of 400 IU (10 mcg) is suggested (9).

**VITAMIN E**
(Tocopherol)

Vitamin E is the generic name for a group of closely related and naturally occurring fat soluble compounds, the tocopherols. Of these alpha-tocopherol is biologically the most potent. Vitamin E is widely distributed in foods. By far the richest sources are vegetable oils, cotton-seed, sunflower seed, egg yolks and butter. Foods rich in polyunsaturated fatty acids are also rich in vitamin E. The usual plasma level of vitamin E in adults is between 0.8 and 1.4 mg per 100 ml (31). While there is no doubt that man requires tocopherol in his diet, there is no clear indication of dietary deficiency. The role of vitamin E at the molecular level is little understood. The current estimate of vitamin E requirement is about 0.8 mg/g of essential fatty acids. This roughly works out to 8–10 mg tocopherol per day depending on the edible oil used (9).

Recently the cytotoxic effect of vitamin E on human lymphocytes in vitro at high concentrations has been reported. This being so, caution should be exercised against the mega-dose consumption of vitamin E in clinical practice.

**VITAMIN K**

Vitamin K occurs in at least two major forms – vitamin K, and vitamin K,. Vitamin K is found mainly in fresh green vegetables particularly dark green ones, and in some fruits. Cow’s milk is a richer source (60 mcg/L) of vitamin K than human milk (15 mcg/L). Vitamin K, is synthesized by the intestinal bacteria, which usually provides an adequate supply in man. Long-term administration of antibiotic doses for more than a week may temporarily suppress the normal intestinal flora, (a source of vitamin K,) and may cause a deficiency of vitamin K. Vitamin K is stored in the liver.

The role of vitamin K is to stimulate the production and/or the release of certain coagulation factors. In vitamin K deficiency, the prothrombin content of blood is markedly decreased and the blood clotting time is considerably prolonged.

The vitamin K requirement of man is met by a combination of dietary intake and microbial synthesis in the gut. The daily requirement for man appears to be about 0.03 mg/kg for the adult. Newborn infants tend to be deficient in vitamin K due to minimal stores of prothrombin at birth and lack of an established intestinal flora. Soon after birth, all infants or those at increased risk should receive a single intramuscular dose of a vitamin K preparation (0.1–0.2 mg of menadione sodium bisulphite or 0.5 mg of vitamin K,) by way of prophylaxis (33).

**Deficiency**

The two principal deficiency diseases are beriberi and Wernicke’s encephalopathy. Beriberi may occur in three main forms: (a) the dry form characterized by nerve involvement (peripheral neuritis); (b) the wet form characterized by heart involvement (cardiac beriberi); and (c) infantile beriberi, seen in infants between 2 and 4 months of age. The affected baby is usually breast-fed by a thiamine-deficient mother who commonly shows signs of peripheral neuropathy. Wernicke’s encephalopathy (seen often in alcoholics) is characterized by ophthalmoplegia, polyneuritis, ataxia and mental deterioration. It occurs occasionally in people who fast.

A few short decades ago, frank cases of beriberi used to be frequently seen in the coastal districts of Andhra Pradesh where people eat highly polished rice. Investigations by the ICMR showed that such cases are now rarely encountered because of improved socio-economic conditions and diversification in the diet consumed now (36).

**Prevention**

Beriberi can be eliminated by educating people to eat well-balanced, mixed diets containing thiamine-rich foods (e.g., parboiled and undermilled rice) and to stop all
alcohol. Direct supplementation of high-risk groups (e.g., lactating mothers) is another approach. Beriberi tends to disappear as economic conditions improve and diets become more varied (10). The disease, as has been shown, is not completely vanquished but the knowledge and resources needed to bring about its disappearance are available (3).

Recommended allowances

The body content of thiamine is placed at 30 mg, and if more than this is given it is merely lost in the urine (19). Patients on regular haemodialysis should routinely be given supplements of thiamine. Thiamine should also be given prophylactically to people with persistent vomiting or prolonged gastric aspiration and those who go on long fasts. For further details see Table 30.

RIBOFLAVIN (B₁)

Riboflavin (Vitamin B₁) is a member of the B-group vitamins. It has a fundamental role in cellular oxidation. It plays an important role in maintaining the integrity of mucocutaneous structure. It is a co-factor in a number of enzymes involved with energy metabolism. It is also involved in antioxidant activity, being a co-factor for the enzymes like glutathione reductase and is required for the metabolism of other vitamins like vitamin B₆, niacin and vitamin K (9).

Sources

Its richest natural sources are milk, eggs, liver, kidney and green leafy vegetables. Meat and fish contain small amounts. Cereals (whether whole or milled) and pulses are relatively poor sources but because of the bulk in which they are consumed, they contribute much of the riboflavin to Indian diets. Germination increases the riboflavin content of pulses and cereals. The riboflavin content of some common foods is given in Table 11.

Source: (34)

Deficiency

The most common lesion associated with riboflavin deficiency is angular stomatitis, which occurs frequently in malnourished children and its prevalence is used as an index of the state of nutrition of groups of children (3). Other clinical signs suggestive (but not specific) include cheilosis, glossitis, nasolabial dysesthesia, etc. In severe, seldom incapacitates the individual, but it may have subtle functional effects such as impaired neuromotor function, wound healing and perhaps increased susceptibility to cataract (37). Riboflavin deficiency almost always occurs in association with deficiencies of other B-complex vitamins such as pyridoxine; it is usually a part of a multiple deficiency syndrome.

Requirement

There are no real body stores of riboflavin. Daily requirement is 0.6 mg per 1000 kcal of energy intake (9). For further details see Table 30.

NIACIN (B₃)

Niacin or nicotinic acid (B₃) is essential for the metabolism of carbohydrate, fat and protein. It is also essential for the normal functioning of the skin, intestinal and nervous systems. This vitamin differs from the other vitamins of the B-complex group in that an essential amino acid, tryptophan serves as its precursor. Another characteristic of niacin is that it is not excreted in urine as such, but is metabolized to at least 2 major methylated derivatives: N-methyl-nicotinamide and N-methyl pyridones.

Sources

Foods rich in niacin and/or tryptophan are liver, kidney meat, poultry, fish, legumes and groundnut. Milk is a poor source of niacin but its proteins are rich in tryptophan which is converted in the body into niacin (about 60 mg of tryptophan is required to result in 1 mg of niacin). In many cereals, especially maize, niacin occurs in “bound” form unavailable to the consumer.

Deficiency

Niacin deficiency results in pellagra. The disease is characterized by three D’s – diarrhoea, dermatitis and dementia. In addition glossitis and stomatitis usually occur. The dermatitis is bilaterally symmetrical and is found only on those surfaces of the body exposed to sunlight, such as back of the hands, lower legs, face and neck. Mental changes may also occur which include depression, irritability and delirium.

Once a formidable and widespread deficiency disease among malnourished population subsisting mainly on maize diets, pellagra has declined in all parts of the world. It is still prevalent in some parts of Western Asia and Southern Africa where people subsist on maize and little else (38). While pellagra is historically a disease of the maize-eating population, it was reported in India in the Telangana area of Andhra Pradesh in some segments of the population eating another cereal – that is jowar (Sorghum vulgare), these people consuming very little of milk or other foods of animal origin. Studies by Gopalan and others (39) have shown that amino- acid imbalance caused by an excess of leucine is the cause of pellagra in both jowar and maize eaters. Excess of leucine appears to interfere in the conversion of tryptophan to niacin.

Prevention

Pellagra is a preventable disease. A good mixed diet containing milk and/or meat is universally regarded as an essential part of prevention and treatment. Avoidance of total dependence on maize or sorghum is an important preventive measure. Pellagra is a disease of poverty. Given modern knowledge and opportunities for economic, agricultural and social development, there is every reason to hope that this disease could be eliminated (3).

Requirement

The recommended daily allowance is 6.0 mg/1000 kcal of energy intake (9). For further details see Table 30.
PYRIDOXINE (B₆)

Pyridoxine (vitamin B₆) exists in three forms: pyridoxine, pyridoxal, and pyridoxamine. It plays an important role in the metabolism of amino acids, fats, and carbohydrates. It is widely distributed in foods, e.g., milk, liver, meat, egg yolk, fish, whole grain cereals, legumes, and vegetables. Pyridoxine deficiency is associated with peripheral neuritis. Riboflavin deficiency impairs the optimal utilization of pyridoxine. INH, an antituberculosis drug, is a recognized antagonist, and patients receiving INH are provided with a supplement of pyridoxine (10 mg/day).

The requirements of adults vary directly with protein intake. Adults may need 2 mg/day; during pregnancy and lactation, 2.5 mg/day. Balanced diets usually contain pyridoxine, therefore deficiency is rare. For further details see Table 30.

PANTOTHENIC ACID (B₃)

There is a long standing evidence for a relation between pantothenic acid and adrenal cortical function. Work indicates a more specific role for pantothenic acid in the biosynthesis of corticosteroids (7). Human blood normally contains 18 to 35 mcg of pantothenic acid per 100 ml, mostly present in the cells as coenzyme A. The daily requirement is set at 10 mg (31). All foods contribute to dietary intake. About 3 mg are excreted daily in urine.

FOLATE

The recommended name is folate, alternative name is folacin and the usual pharmaceutical preparation is folic acid (19).

Folic acid occurs in food in two forms: free folates and bound folates. The total folates represent both the groups. In man, free folate is rapidly absorbed, primarily from the proximal part of small intestine. The availability of bound folate is uncertain. Folic acid plays a role in the synthesis of the nucleic acids (which constitute the chromosomes). It is also needed for the normal development of blood cells in the marrow.

Sources

The name comes from the Latin folia (= leaf) but foods such as liver, meat, dairy products, eggs, milk, fruits, and cereals are as good dietary sources as leafy vegetables. Overcooking destroys much of folic acid and thus contributes to folate deficiency in man. Folate deficiency has been reported in babies given milk foods subjected to heat sterilization.

Deficiency

Folate deficiency may occur simply from a poor diet. It is commonly found in pregnancy and lactation (40) where requirements are increased. It results in megaloblastic anaemia, glossitis, cheilosis, and gastrointestinal disturbances such as diarrhoea, distension and flatulence. Severe folate deficiency may cause infertility or even sterility. There is also evidence that the administration of folic acid antagonists (e.g., alcohol, pyrimethamine, and cotrimoxazole) in early pregnancy may produce abortions or congenital malformations.

The laboratory diagnosis of folate deficiency is based on measurement of serum and red cell folate concentrations, usually by microbiological assay (41).

Requirement

Body stores of folate are not large, about 5–10 mg, and therefore, folate deficiency can develop quickly. Folic acid requirements are greater in conditions where there is rapid cell multiplication, such as during growth in young children and during pregnancy (41). Folic acid supplementation during pregnancy has been found to increase the birth weight of infants and decrease the incidence of low birth weight babies. Intake values recommended by ICMR (2010) are given below:

VITAMIN B₁₂

Vitamin B₁₂ is complex organo-metallic compound with a cobalt atom. The preparation which is therapeutically used is cyanocobalamin, which is relatively cheap. Vitamin B₁₂ cooperates with folate in the synthesis of DNA, so deficiency of either leads to megaloblastosis. Vitamin B₁₂ has a separate biochemical role, unrelated to folate, in synthesis of fatty acids in myelin (19). The physiological mechanism for its absorption requires intrinsic factor from the stomach, and the complex is absorbed only at a special site in the terminal ileum.

Sources

Good sources are liver, kidney, meat, fish, eggs, milk, and cheese. Vitamin B₁₂ is not found in foods of vegetable origin. It is also synthesized by bacteria in colon. Unlike folic acid, vitamin B₁₂ is relatively heat stable. Liver is the main storage site of vitamin B₁₂. About 2 mg are stored in liver, and another 2 mg elsewhere in the body. These stores are sufficient to tide over any deficiency for one to three years. Because of these reserves, deficiency of vitamin B₁₂ appears to be rare.

Deficiency

Vitamin B₁₂ deficiency is associated with megaloblastic anaemia (pernicious anaemia), demyelinating neurological lesions in the spinal cord and infertility (in animal species); which is rarely seen in India. While clinical deficiency of B₁₂ is not manifested, sub-clinical deficiency is reported to exist in India. Reports indicate that there exist more than 30 per cent deficiency in adults and children in the country. It is not surprising that blood levels of vitamin B₁₂ are low, since a large proportion of population depends on plant food for nutrients (9).

VITAMIN C

Vitamin C (ascorbic acid) is a water-soluble vitamin. It is the most sensitive of all vitamins to heat. Man, monkey and guinea pig are perhaps the only species known to require vitamin C in their diet.

Functions

Vitamin C is a potent antioxidant and has an important role to play in tissue oxidation. It is needed for the formation of collagen, which accounts for 25 per cent of total body protein (7). Collagen provides a supporting matrix for the blood vessels and connective tissue, and for bones and cartilage. That explains why in vitamin C deficiency this support fails, with the result that local haemorrhages occur and the bones fracture easily. Vitamin C, by reducing ferric iron to ferrous iron, facilitates the absorption of iron from vegetable foods. It inhibits nitrosamine formation by the intestinal mucosa. Other claims such as prevention of common cold and protection against infections are not substantiated.

Sources

The main dietary sources of vitamin C are fresh fruits and green leafy vegetables. Traces of vitamin C occur in fresh meat and fish but scarcely in cereals. Germinating pulses contain good amounts. Roots and tubers contain small amounts. Amla or the Indian gooseberry is one of the richest sources of vitamin C both in the fresh as well as in the dry condition. Guavas are another cheap but rich source of this vitamin. The dietary sources of vitamin C are as given in Table 12.

Source: (34)

Deficiency

Deficiency of vitamin C results in scurvy, the signs of which are swollen and bleeding gums, subcutaneous bruising or bleeding into the skin or joints, delayed wound healing, anaemia and weakness. Scurvy which was once an important deficiency disease is no longer a disease of world importance (3).

Requirement

The estimated requirement for vitamin C is 40 mg per day for adults. The normal body when fully saturated contains about 5 g of vitamin C. Daily intakes recommended by the ICMR (9) are as given in Table 30.

MINERALS

More than 50 chemical elements are found in the human body, which are required for growth, repair and regulation of vital body functions. These can be divided into three major groups: (a) MAJOR MINERALS: These include calcium, phosphorus, sodium, potassium and magnesium; (b) TRACE ELEMENTS: These are elements required by the body in quantities of less than a few milligrams per day, e.g., iron, iodine, fluorine, zinc, copper cobalt, chromium, manganese, molybdenum, selenium, nickel, tin, silicon and vanadium (41). Many more have been added to the list in the last few years; and (c) TRACE CONTAMINANTS WITH NO KNOWN FUNCTION: These include lead, mercury, barium, boron, and aluminium.

Only a few mineral elements (e.g., calcium, phosphorus, potassium, sodium, iron, fluorine, iodine) are associated with clearly recognizable clinical situations in man. For none of the other elements do we know with any certainty for their metabolic roles, and much less the clinical effects of dietary insufficiency (42). The bio-availability of minerals such as iron and zinc may be low in a total vegetarian diet because of the presence of substances such as phytic acid. Besides, large amounts of dietary fibre may interfere with proper absorption. Man is not likely to suffer from trace element deficiencies as long as he is omnivorous. Surveys have shown that mineral deficiencies are no greater among vegetarians than among non-vegetarians. In fact, man's need for trace elements has not yet been precisely determined. Trace elements should not be used as dietary supplements, since excessive amounts can have injurious effects.

CALCIUM

Calcium is a major mineral element of the body. It constitutes 1.5–2 per cent of the body weight of an adult human. An average adult body contains about 1200 g of calcium of which over 98 per cent is found in the bones. The amount of calcium in the blood is usually about 10 mg/dl. The developing foetus requires about 30 g of calcium. There is a dynamic equilibrium between the calcium in the blood and that in the skeleton; this equilibrium is maintained by the interaction of vitamin D, parathyroid hormone, and probably calcitonin.

Functions

Ionized calcium in the plasma has many vital functions including formation of bones and teeth, coagulation of blood, contraction of muscles, cardiac action, milk production, relay of electrical and chemical messages that arrive at a cell's surface membrane to the biochemical machinery within the cell, keeping the membranes of cells intact and in the metabolism of enzymes and hormones. It also plays a crucial role in the transformation of light to electrical impulses in the retina. In short, the calcium ion controls many life processes ranging from muscle contraction to cell division.

Sources

Calcium is readily available from many sources. By far the best natural sources are milk and milk products, e.g., cheese, curd, skimmed milk and butter milk, eggs and fish. A litre of cow's milk provides about 1200 mg of calcium, and human milk about 300 mg. Calcium occurs in milk as
**Calcium**

Calcium is an essential mineral for the human body. It is found in all body fluids and is vital for various physiological functions. The adult human body contains about 1000 g of calcium, with 99% of it being stored in bone and teeth. Calcium is important for bone and teeth health, blood clotting, muscle and nerve function, and the regulation of body processes.

**Absorption**

Calcium absorption is regulated by the body's needs. Overall, about 20–30% of dietary calcium is normally absorbed. Absorption of calcium is enhanced by vitamin D and decreased by the presence of oxalates, phytates, and fatty acids in the diet. Calcium absorption is regulated to some extent by the body's needs.

**Deficiency**

Calcium deficiency is rare because the body has mechanisms to conserve calcium. Deficiency may occur in conditions such as malabsorption, chronic alcoholics, cirrhosis of liver, and certain medical conditions. Deficiency may also occur in infants and young children who are not consuming enough calcium in their diet.

**Requirement**

The ideal desirable calcium intake recommended by ICMR (9) is 400 mg/day for children, expectant and nursing mothers. For adults, the recommended intake is 600 mg/day. The intake values recommended by ICMR (9) are as given in Table 29.

**Phosphorus**

Phosphorus is essential for the formation of bones and teeth. It plays an important role in all the major metabolic processes of the body. The adult human body contains about 1000 g of phosphorus, with 90% of it being stored in the bones and teeth. Phosphorus is also an important component of cell membranes, energy transfer, and the regulation of metabolic processes.

**Absorption**

Phosphorus absorption is regulated to some extent by the body's needs. Overall, about 20–30% of dietary phosphorus is normally absorbed. Absorption of phosphorus is enhanced by vitamin D and decreased by the presence of oxalates and phytates in the diet. Phosphorus absorption is regulated to some extent by the body's needs.

**Deficiency**

Phosphorus deficiency is rare because the body has mechanisms to conserve phosphorus. Deficiency may occur in conditions such as malabsorption, chronic alcoholics, cirrhosis of liver, and certain medical conditions. Deficiency may also occur in infants and young children who are not consuming enough phosphorus in their diet.

**Requirement**

The ideal desirable phosphorus intake recommended by ICMR (9) is 400 mg/day for children, expectant and nursing mothers. For adults, the recommended intake is 1000 mg/day. The intake values recommended by ICMR (9) are as given in Table 29.

**Sodium**

Sodium is found in all body fluids. The adult human body contains about 100 g of sodium. Sodium occurs in many foods, and is also added to food during cooking in the form of sodium chloride. Sodium is lost from the body through urine and sweat; that which is passed out in urine is regulated by the kidney but that which is lost by sweating is not controlled. Depletion of sodium chloride causes muscular cramps. The requirement of sodium chloride depends upon climate, occupation and physical activity. Adult requirement is about 7 g per day. A strong relationship between dietary salt intake has been observed and intake of more than 10 g of salt per day is considered to have definitive tendency to raise blood pressure (9).

**Potassium**

The adult human body contains about 250 g of potassium. Potassium occurs widely in foods, so there is little likelihood of its deficiency. Potassium is vasoactive, increases blood flow and sustains metabolic needs of the tissue. Potassium is released by endothelial cells. Potassium supplements lower blood pressure, although the response is slow. Much of the information regarding potassium and blood pressure is in relation to dietary sodium. High dietary sodium, low dietary potassium have been implicated in the aetiology of hypertension as evidenced by epidemiological clinical studies (9).

The ideal desirable sodium : potassium ratio in the diet is 1.1 (in mmol).

**Magnesium**

Magnesium is a constituent of bones, and is present in all body cells. Human adult body contains about 25 g of magnesium of which about half is found in the skeleton. Magnesium deficiency may occur in chronic alcoholics, cirrhosis of liver, toxemia of pregnancy, protein-energy malnutrition and the malabsorption syndrome (46). The principal clinical features attributed to magnesium deficiency are irritability, tetany, hyper-reflexia and occasionally hypo-reflexia. Requirements are estimated to be about 340 mg/day for adults (9). For details see Table 29.

**Iron**

Iron is of great importance in human nutrition. The adult human body contains between 3–4 g of iron, of which about 60–70% is present in the blood (Hb iron) as circulating iron, and the rest (1 to 1.5 g) as storage iron. Each gram of haemoglobin contains about 3.34 mg of iron.

**Functions**

Iron is necessary for many functions in the body including formation of haemoglobin, brain development and function, regulation of body temperature, muscle activity, and catecholamine metabolism. Lack of iron directly affects the immune system; it diminishes the number of T-cells and the production of antibodies. Besides haemoglobin, iron is a component of myoglobin, the cytochromes, catalase and certain enzyme systems. Iron is essential for binding oxygen to the blood cells. The central function of iron is "oxygen transport", and cell respiration.

**Sources**

There are two forms of iron, haem-iron and non-haem iron. Haem-iron is better absorbed than non-haem iron. Foods rich in haem-iron are liver, meat, poultry and fish.
When red cells are broken down, the liberated iron is a characteristic feature of iron metabolism. It is conserved and stored in liver, spleen, bone marrow, and kidney. The absorption from habitual Indian diets is less than 5 per cent of the requirement for iron, as for example during pregnancy. Iron is absorbed in the duodenum and jejunum (e.g., coeliac disease, tropical sprue). Iron absorption is greater when there is an increased demand for iron, as for example during pregnancy. Iron absorption from habitual Indian diets is less than 5 per cent (17), the bioavailability being poor.

The absorbed iron is transported as plasma ferritin and stored in liver, spleen, bone marrow, and kidney. The characteristic feature of iron metabolism is conservation. When red cells are broken down, the liberated iron is reutilized in the formation of new red cells.

Iron is mostly absorbed from the duodenum and upper small intestine in the ferrous state, according to body needs. The rate of iron absorption is influenced by a great many factors like iron reserves of the subjects, the presence of inhibitors (e.g., phosphates), and promoters (e.g., ascorbic acid and ascorbic acid-rich foods) of iron absorption, and disorders of duodenum and jejunum (e.g., coeliac disease, tropical sprue). Iron absorption is greater when there is an increased demand for iron, as for example during pregnancy. Iron absorption from habitual Indian diets is less than 5 per cent (17), the bioavailability being poor.

The absorbed iron is transported as plasma ferritin and stored in liver, spleen, bone marrow, and kidney. The characteristic feature of iron metabolism is conservation. When red cells are broken down, the liberated iron is reutilized in the formation of new red cells.

**Iron losses**

The total daily iron loss of an adult is probably 1 mg, and about 12.5 mg per 28 days cycle in menstruating women. Major routes of iron loss are: (a) through haemorrhage, that is, wherever blood is lost, iron is lost, the causes of which may be physiological (e.g., menstruation, childbirth) or pathological (e.g., hookworms, malaria, haemorrhoids, peptic ulcers); (b) basal losses, such as excretion through urine, sweat, and bile, and desquamated surface cells. The widespread use of IUDs in the family planning programme is an additional cause of iron loss. IUDs have been shown to increase the average monthly blood loss by between 35 and 146 per cent depending upon the type of the device (49, 50). Hormonal contraceptives, on the other hand, decrease menstrual blood loss by about 50 per cent (51).

**Iron deficiency**

Three stages of iron deficiency have been described: (a) First stage characterized by decreased storage of iron without any other detectable abnormalities. (b) An intermediate stage of "latent iron deficiency," that is, iron stores are exhausted, but anaemia has not occurred as yet. Its recognition depends upon measurement of serum ferritin levels. The percentage saturation of transferrin falls from a normal value of 30 per cent to less than 15 per cent. This stage is the most widely prevalent stage in India. (c) The third stage is that of overt iron deficiency when there is a decrease in the concentration of circulating haemoglobin due to impaired haemoglobin synthesis (49).

The end result of iron deficiency is nutritional anaemia which is not a disease entity. It is rather a syndrome caused by malnutrition in its widest sense (51). Besides anaemia, there may be other functional disturbances such as impaired cell-mediated immunity, reduced resistance to infection, increased morbidity and mortality, and diminished work performance.

**Diagnosis of anaemia**

A WHO Expert Group (52) proposed that "anaemia or deficiency should be considered to exist" when haemoglobin is below the following levels (see Table 13).

**EVALUATION OF IRON STATUS**

Evaluation of iron status is based on the following parameters:

(a) **Haemoglobin concentration**: Values below those given in Table 13 indicate anaemia. Haemoglobin concentration is a relatively insensitive index of nutrient depletion. Its value is less in population groups in which anaemia is not severe. This is because anaemia is a late manifestation of iron deficiency which frequently occurs without the manifestation of anaemia (52).

(b) **Serum iron concentration**: This is a more useful index than haemoglobin concentration. The normal range is 0.80 to 1.80 mg/L; values below 0.50 mg/L indicate probable iron deficiency (54).

(c) **Serum ferritin**: The single most sensitive tool for evaluating the iron status is by measurement of serum ferritin. It reflects the size of iron stores in the body. It is the most useful indicator of iron status in a population where the prevalence of iron deficiency is not high. Values below 10 mcg/L probably indicate an absence of stored iron (19).

(d) **Serum transferrin saturation**: This should be above 16 per cent. Normal value is 30 per cent.

**Iron requirements**

Because of the recycling of iron, only a small amount of iron is needed by the body. In general, iron requirements are greater when there is rapid expansion of tissue and red cell mass, as for example during pregnancy, childhood & adolescence. Table 14 shows the recommended daily intakes.

Source: (9)

The recommended dietary intakes of iron are as given in Table 29.

IODINE

Iodine is an essential micronutrient. It is required for the synthesis of the thyroid hormones, thyroxine (T₄) and triiodothyronine (T₃), containing respectively 4 and 3 atoms of iodine. Iodine is essential in minute amounts for the normal growth and development and well-being of all humans. The adult human body contains about 50 mg of iodine, and the blood level is about 8–12 micrograms/dl (31).

Sources

The best sources of iodine are sea foods (e.g., sea fish, sea salt) and cod liver oil. Smaller amounts occur in other foods, e.g., milk, meat, vegetables, cereals, etc. The iodine content of fresh water is small and very variable, about 1–50 micrograms/L (31).

About 90 per cent of iodine comes from foods eaten; the remainder from drinking water. The iodine content of the soil determines its presence in both water and locally grown foods. The deficiency is geochemical in nature.

Goitrogens

“Goitrogens”, are chemical substances leading to the development of goitre. They interfere with iodine utilization by the thyroid gland. They may occur in food and water. The brassica group of vegetables (e.g., cabbage, cauliflower) may contain goitrogens. Most important among the dietary goitrogens are probably cyanoglycosides and the thiocyanates.

Deficiency

The most obvious consequence of iodine deficiency is goitre but recent studies have indicated that there is a much wider spectrum of disorders, some of them so severe as to be disabling. They include: (a) hypothyroidism (b) retarded physical development and impaired mental function (c) increased rate of spontaneous abortion and stillbirth (d) neurological cretinism, including deaf-mutism; and (e) myxoedematous cretinism, including dwarfism and severe mental retardation. To express this state of affairs more accurately, the term “endemic goitre”, is now replaced by the term Iodine Deficiency Disorders (IDD) to refer to all the effects of iodine deficiency on human growth and development which can be prevented by correction of iodine deficiency (55, 56, 57). The spectrum of IDD is as shown in Table 15.

</tbody>
</table>

It can be seen from Table 15 that the problem of IDD is of far greater magnitude than one of goitre and cretinism. It is a national problem with grave socio-economic consequences. Adequate technology exists for the successful prevention of iodine deficiency disorders (see page 680).

Requirement

The daily requirement of iodine for adults is placed at 150 micrograms. The recommendations of WHO of 250 mcg per day for iodine during pregnancy have also been adopted. This amount is normally supplied by well-balanced diet and drinking water except in regions where food and water are deficient in iodine.

Epidemiological assessment of iodine deficiency

This is necessary before initiating an iodization programme, and for surveillance of goitre control.
procedures. The following indicators are useful in this regard (58):

- prevalence of goitre;
- prevalence of cretinism;
- urinary iodine excretion;
- measurement of thyroid function by determination of serum levels of thyroxine (T\textsubscript{4}) and pituitary thyrotropic hormone (TSH); and
- prevalence of neonatal hypothyroidism.

Since the objective of goitre control programme is to increase iodine intake, indices of urinary excretion are particularly recommended for use in surveillance. Neonatal hypothyroidism has been found to be a sensitive indicator of environmental iodine deficiency. Serum T\textsubscript{4} level is a more sensitive indicator of thyroid insufficiency than T\textsubscript{3}.

FLUORINE

Fluorine is the most abundant element in nature. Being so highly reactive, it is never found in its elemental gaseous form, but only in combined form. About 96 per cent of the fluoride in the body is found in bones and teeth. Fluorine is essential for the normal mineralization of bones and formation of dental enamel.

Sources

The principal sources of fluorine available to man are:

(a) Drinking water: The major source of fluorine to man is drinking water. In most parts of India, the fluoride content of drinking water is about 0.5 mg/L, but in fluorosis-endemic areas, it may be as high as 3 to 12 mg/L (59).

(b) Foods: Fluorides occur in traces in many foods, but some foods such as sea fish, cheese and tea are reported to be rich in fluorides (38).

Deficiency/excess

Fluorine is often called a two-edged sword. Prolonged ingestion of fluorides through drinking water in excess of the daily requirement is associated with dental and skeletal fluorosis; and inadequate intake with dental caries. The use of fluorine is recognized as the most effective means available for the prevention of dental caries.

Requirements

The recommended level of fluorides in drinking water in India is accepted as 0.5 to 0.8 mg per litre (60, 61). In temperate countries where the water intake is low, the optimum level of fluorides in drinking water is accepted as 1 to 2 mg per litre (62).

OTHER TRACE ELEMENTS

Zinc

Zinc is a component of more than 300 enzymes. It is active in the metabolism of glucides and proteins, and is required for the synthesis of insulin by the pancreas and for the immunity function. Zinc is present in small amounts in all tissues. Zinc-plasma level is about 96 μg per 100 ml for healthy adults, and 89 μg per 100 ml for healthy children (63). The average adult body contains 1.4 to 2.3 g of zinc (64). Zinc deficiency has been reported to result in growth failure and sexual infantilism in adolescents, and in loss of taste and delayed wound healing (10). There are also reports of low circulating zinc levels in clinical disorders such as liver disease, pernicious anaemia, thalassaemia and myocardial infarction. Zinc deficiency is common in children from developing countries due to lack of intake of animal food, high dietary phytate content, inadequate food intake and increased faecal losses during diarrhoea. Zinc supplementation in combination with oral rehydration therapy has been shown to significantly reduce the duration and severity of acute and persistent diarrhoea and to increase survival in a number of randomised control trials. Adequate zinc intake is essential for maintaining the integrity of immune system. Zinc affects multiple aspects of the immune system, from the barrier of the skin to gene regulation within lymphocytes. Severe maternal zinc deficiency has been associated with spontaneous abortion and congenital malformations like anencephaly. Milder forms of zinc deficiency have been associated with low birth weight, intrauterine growth retardation and preterm delivery. Several studies have indicated that zinc supplementation may reduce the incidence of clinical attacks of malaria in children. Zinc plays an important role as an antioxidant agent (65). These reports suggest that zinc deficiency may not be uncommon in man (63). Zinc is widely distributed in foodstuffs, both animal and vegetable—but the bioavailability of zinc in vegetable foods is low. Animal foods such as meat, milk and fish are dependable sources. Suggested daily intake for adults is 12 mg per day for men, 10 mg per day for women, 10 mg per day for children and 5 mg for infants. Refer to Table 29 for details. Growing children and pregnant and lactating women need more. Most human diets provide these amounts.

Copper

The amount of copper in an adult body is estimated to be between 100–150 mg. Copper is widely distributed in nature. Even poor diets provide enough copper for human needs. Deficiency or excess of this element is very rare. Hypocupremia occurs in patients with nephrosis, Wilson's disease and protein-energy malnutrition and in infants fed for long periods exclusively on cow's milk. Neutropenia is the best documented abnormality of copper deficiency. Hypercupremia may reflect excessive intake which may result from eating food prepared in copper cooking vessels, or it may be associated with several acute and chronic infections (leukaemia, Hodgkin's disease, severe anaemia, haemochromatosis, myocardial infarction and hyperthyroidism (66). Estimated copper requirement for adults is about 2.0 mg per day.

Cobalt

The only established function of cobalt in the human is as a part of the vitamin B\textsubscript{12} molecule, which must be ingested preformed. There is no evidence as yet of cobalt deficiency in man (10). Recently cobalt deficiency and cobalt iodine ratio in the soil have shown to produce goitre in humans. It is suggested that cobalt may be necessary for the first stage of hormone production, i.e., capture of iodine by the gland (67). Cobalt may interact with iodine and affect its utilization (10).

Chromium

Total body content of chromium is small, less than 6 mg. Current interest in chromium is based on the occurrence of unusual glucose tolerance curves that are responsive to chromium (41). Thus there is suggestive evidence that chromium plays a role in relation to carbohydrate and insulin function (10).
Selenium

Little attention had been given earlier to selenium in human nutrition. The first report that selenium deficiency may occur in man appeared in 1961, and a similar report in 1967. Selenium administration to children with kwashiorkor resulted in significant weight increase. Studies indicate that human selenium deficiency may occur in protein-energy malnutrition (66). Selenium deficiency especially when combined with vitamin E deficiency, reduces antibody production (68).

Molybdenum

Excess absorption of molybdenum has been shown to produce bony deformities. On the other hand, deficiency of molybdenum is associated with mouth and oesophageal cancer (67).

Dietary antioxidants (9)

Antioxidants are substances which are both nutrients, viz. vitamins E, C, B-carotene, selenium, and non-nutrients, viz. plant phenols, flavonoids, coumarins, benzyl isothiocyanates, caffeic, ferrulic, gallic and ellagic acids, some enzymes like superoxide dismutase and catalase superoxides mutase. These antioxidants reduce the adverse effects of reactive oxygen species (ROS) and nitrogen species which are generated during physiological or pathological conditions and result in oxidant damage. Literature is replete with evidence that ageing and several diet/nutrient related chronic disorders are due to chronic exposure to ROS. It is well established that vegetables, fruits, legumes, spices, beverages such as tea and wine, and cereals are excellent sources of AO, however scientific evidence for their protective role is available only for vegetables and fruits in several chronic disorders. None of the randomized clinical trials conducted so far with nutrient AO supplements has demonstrated a significant benefit in community trials barring one or two major trials in high-risk populations.

Experimental studies have amply indicated that both pro-oxidant and AO have a fundamental role in pathogenesis of diseases. Reactive oxygen species (ROS) damage the bio-molecules such as DNA, protein, carbohydrates and lipids, and affect the enzyme processes and genetic machinery. The oxidation products of bio-molecules accumulate with age. ROS can be derived from an environmental source also. There are several endogenous and exogenous sources of ROS, which play an important role in diseases such as cardiovascular, cancer, cataract, diabetes, neuro-degenerative disorders and age-related masculopathy. Chronic infections aggravate the damage. Further, research in this field has highlighted the mechanistic details about the role of antioxidants in mitigating the damage.

Free radicals produced during tissue metabolism and their consequent damage are reduced by nutrient antioxidants. The antioxidants, particularly vitamin E, C, co-enzyme Q and glutathione seem to work in concert by recycling each other.

In healthy subjects, the dietary antioxidants from a balanced diet with adequate fruits and vegetables ranging from 500-600 gm/d will probably be enough to take care of oxidant damage and repair cellular and tissue defects. However, certain groups of populations like pre-mature infants, smokers, alcoholics, and those exposed to environmental pollutants including carcinogens, individuals with chronic infections as well as those engaged in strenuous physical activity and geriatric population, are at high-risk of oxidant damage.

At present the amount of antioxidants to be consumed daily to protect against risk factors cannot be quantitatively fixed (9).

NUTRITIONAL PROFILES OF PRINCIPAL FOODS

When planning balanced diets, it is important to know what foods are available according to origin, approximate chemical composition, predominant function and how to combine them to increase nutritive value. Since each food has a different nutritional profile, an intake of different types of foods is desired to achieve optimum health.

1. Cereals and millets

Cereals (e.g., rice, wheat) constitute the bulk of the daily diet. Rice is the staple food of more than half the human race. Next to rice, wheat is the most important cereal. Maize ranks next to rice and wheat in world consumption. Maize is also used as food for cattle and poultry because it is rich in fat, besides being cheaper than rice or wheat.

Cereals are the main sources of energy (carbohydrates). They also contribute significant quantities of proteins (6 to 12 per cent), minerals and B-group vitamins. The yellow variety of maize contains significant amounts of carotene. In terms of energy, cereals provide about 350 kcal per 100 grams. Considering the large amounts in which they are consumed, cereals contribute 70 to 80 per cent of the total energy intake, and more than 50 per cent of protein intake in typical Indian diets.

Cereal proteins are poor in nutritive quality, being deficient in the essential amino acid, lysine. The proteins of maize are still poorer, being deficient in lysine and tryptophan (a precursor of niacin). However, if cereals are eaten with pulses, as is common in the traditional Indian diets, cereal and pulse proteins complement each other and provide a more balanced and "complete" protein intake. Some strains of maize contain an excess of leucine which interferes with the conversion of tryptophan into niacin; this aggravates the pellagragenic action of maize.

Table 16 gives the nutritive value of some common cereals.

Source [134]
Rice

Rice is the staple food of more than half the human race. The rice grain consists of 3 parts — the germ (embryo), the inner endosperm, and the outer pericarp and aleurone grain layer. The endosperm is composed mostly of starch; the outer pericarp layer and aleurone layer contain most of the essential nutrients. The protein content of rice varies from 6-9 per cent. Rice proteins are richer in lysine than the other cereal proteins, and for this reason, rice protein is considered to be of better quality. Rice is a good source of B group vitamins, especially thiamine. It is devoid of vitamins A, D and C. In regard to minerals rice is a poor source of calcium and iron (Table 17).

**Effect of milling**

The milling process deprives the rice grain of its valuable nutritive elements (thiamine, riboflavin, protein). The losses may be up to 15 per cent of protein, 75 per cent of thiamine and 60 per cent of riboflavin and niacin (69). The resulting white or polished rice, although attractive in appearance, is poor in nutritive value. People subsisting mainly on white or polished rice are prone to beriberi, the best known deficiency disease of rice eaters. Nutrition workers therefore advocate under-milled or “parboiled” rice in place of white rice.

**Washing and cooking**

The rice grain is subjected to further loss of essential nutrients during the process of washing and cooking. Washing in large quantities of water would remove up to 60 per cent of the water-soluble vitamins and minerals. The practice of cooking rice in large quantities of water and draining away the excess of water at the end of cooking leads to further loss of B-group vitamins. Thus the combined effect of washing and cooking may affect seriously the nutritive value of rice. It is therefore best to cook rice in just enough water (about 2 measure of water for 1 measure of rice).

**Parboiling**

Parboiling (partial cooking in steam) is ancient Indian technique of preserving the nutritive quality of rice. There are many techniques of parboiling. The technique recommended by the Central Food Technical Research Institute, Mysore (8) is known as the hot soaking process.

The process starts with soaking the unhusked rice in hot water at 65 to 70 deg. C for 3 to 4 hours, which swells the grain. This is followed by draining of water and steaming the soaked paddy in the same container for 5 to 10 minutes. The paddy is then dried and later homepounded or milled.

During the steaming process, a greater part of the vitamins and minerals present in the outer aleurone layer of the rice grain are driven into the inner endosperm. Subsequent milling, even to a high degree, the nutrients are not removed. During the drying process, the germ gets attached more firmly to the grain. In addition, the heat used in drying hardens the rice grain. It results in the grain becoming more resistant to insect invasion and more suitable for storage than raw rice. The starch also gets gelatinized which improves the keeping quality of rice.

The serious disadvantage of parboiling is the development of a peculiar smell or “off flavour” which some consumers do not relish. Modern methods of parboiling rice have been developed by which the finished product does not give any bad odour.

**Wheat**

Next to rice, wheat is the most important cereal. The nutritive composition of wheat is given in Table 16. The protein content of wheat varies from 9 to 16 per cent, the limiting amino-acids are lysine and threonine. The wheat grain is much less subjected to loss of essential nutrients during processing than rice. In India, the bulk of wheat is consumed as whole grain wheat flour or atta. Maida or white flour which represents 70 per cent extraction of wheat is poorer from the nutrition standpoint. The whiter the flour the greater the loss of vitamins and minerals. Thus whole grain wheat flour is richer source of vitamin B than refined white flour.

**Maize**

Maize (Corn, bhutta) ranks next to rice and wheat in world consumption, and in certain areas it is the principal source of proteins and energy both. It is also used as a food for cattle and poultry. The yellow variety of maize contains significant amount of carotenoid pigments. Maize is fairly rich in fat (Table 16). The proteins of maize are deficient in tryptophan and lysine; and some strains contain an excess of leucine. Studies indicate that excess of leucine interferes in the conversion of tryptophan into niacin, and thus aggravates the pellagragenic action of maize. Maize is also used in the manufacture of breakfast foods such as cornflakes. Maize flour or corn flour is widely used in the preparation of custards and table desserts. The incorporation of opaque-2 gene into maize has greatly improved the quality of its protein.

**MILLETS**

The term “millet” is used for smaller grains which are ground and eaten without having the outer layer removed; they are jowar (sorghum), bajra (pearl millet), ragi, kodo and a few others known as “minor millets” or pseudocereals (70). The nutritive value of millets is as shown in Table 18.
Jowar (sorghum)

Jowar is also known as kaffir corn or Milo. It is a major crop grown in India next only to wheat and rice. For several population groups, it is a staple diet. The protein content of jowar varies from 9 to 14 per cent, and the proteins are limiting in lysine and threonine. Certain varieties of jowar have a high leucine content and consumption of these varieties is associated with pellagra. This disorder is often seen in the Telengana and Marathwada regions where jowar is predominantly consumed.

Bajra (pearl millet)

Bajra is grown extensively in the dry belts of northern and peninsular India, viz. Rajasthan, Gujarat and Maharashtra, where it forms the staple food of large sections of the population. The protein content varies from 10 to 14 per cent; the proteins are deficient in lysine and threonine. Bajra contains significant amounts of B-group vitamins and minerals such as calcium and iron.

Ragi

Ragi is a popular millet in Andhra and Karnataka. It is the cheapest among millets. Ragi flour is cooked and eaten as porridge. Ragi is rich in calcium (see Table 18).

2. Pulses (legumes)

Pulses comprise a variety of grams, also known as dhals. Most commonly eaten pulses are bengal gram (chana), red gram (tuar or arhar), green gram (mung) and black gram (urad). Others include lentils (masur), peas and beans including soyabean. Khesari dhal (lathyrus sativus), is consumed in parts of Madhya Pradesh, Uttar Pradesh and peninsular India, viz. Rajasthan, Gujarat and Maharashtra, where it forms the staple food of large sections of the population. The protein content varies from 10 to 14 per cent; the proteins are deficient in lysine and threonine. Bajra contains significant amounts of B-group vitamins and minerals such as calcium and iron.

Ragi

Ragi is a popular millet in Andhra and Karnataka. It is the cheapest among millets. Ragi flour is cooked and eaten as porridge. Ragi is rich in calcium (see Table 18).

Anti-nutritional factors: In the raw state, pulses have some anti-nutritional factors such as phytates and tannins which adversely affect the availability of some nutrients to the body. However, most of the anti-nutritional factors are destroyed by heat. Presence of high amounts of certain sugars known as oligosaccharides is known to be associated with flatulence.

3. Vegetables

Vegetables are classed as “protective foods”; their value resides in their high vitamin and mineral content. Some vegetables (e.g., green peas, beans) are also good sources of protein. Vegetables usually have a large water content, low energy and protein content and varying amounts of “dietary fibre”. Vegetables are divided into three groups “green leaves”; “roots and tubers”; and “others”.

a. Green leaves

The term “green leaves” designates a number of indigenous leafy vegetables consumed by the people. They include palak (spinach), amaranth, cabbage, fenugreek (methi) etc. The darker the green leaves, the greater their nutritive value. With the possible exception of vitamin B₁₂, green leaves are rich sources of carotenes, calcium, iron and vitamin C. They are also good sources of riboflavin, folic acid and many other micronutrients. In addition, leaf proteins (2 to 4 per cent) are good sources of lysine, although deficient in sulphur – containing amino acids. The bioavailability of calcium and iron from greens is rather poor because of the presence of high amounts of oxalates. Leafy vegetables are high in water content and dietary fibre. Because of their low caloric value (25 to 50 kcal per 100 g)

and large bulk, they have an important place in the dietaries of obese people who wish to cut down their calorie intake. The recommended daily intake of green leafy vegetables is about 40 g for an adult.

b. Roots and tubers

Included in this group are potato, sweet potato, tapioca, yam, carrots, onion, radish and colocasia. They vary widely in composition, some are good sources of carbohydrates such as potatoes and tapioca. In general roots and tubers are poor in protein, minerals and vitamins. Carrots are exceptionally high in betacarotene. In times of cereal shortage, potatoes, sweet potatoes, and tapioca can serve as subsidiary foods for limited periods. But bulk and low protein make them unsuitable as staple foods for longer periods, unless supplemented by foods richer in protein. The recommended daily intake of roots and tubers is 50 to 60 g for an adult.

c. Other vegetables

There is a wide range of “other” vegetables such as brinjal, tomatoes, cauliflower, etc. They bring variety to the diet. Many of them are fairly good sources of minerals and vitamins. Some vegetables like cluster beans, drumsticks and green mango contain fair amounts of iron. The daily recommended intake is 60 to 70 grams.

4. Nuts and oilseeds

Included in this group are groundnut (Peanut), cashewnut, coconut, walnut, almonds, pistachio, mustard seeds, sesame seeds, cotton seeds, sunflower seeds, maize germ and many others from which cooking oils are extracted.

Nuts and oilseeds contain good amount of fat and good quality protein in a relatively small bulk. Regarding the fat content, peanuts contain 64.5 per cent, almonds 58.7 per cent, cashewnuts 46.9 per cent and groundnut 40 per cent. Peanut (groundnut) butter is a very valued article of the diet. Regarding protein content, groundnut tops the list with 26.7 per cent. Being of vegetable origin, their protein is not equal to that of meat or eggs in quality. Nuts are good sources of vitamins of the B-group. They contribute minerals such as calcium, phosphorus, and iron. Among the commonly used nuts, cashewnuts and almonds are good sources of iron, but pistachio is the richest containing 14 mg of iron per 100 g.

Most of the vegetable oils are rich in essential fatty acids. After oil extraction in the case of some, the residue (oilseed cake) can be formulated into acceptable foods rich in protein. For example, groundnut flour is used in the manufacture of Indian Multipurpose Food, balahar and balanced malt food. Due partly to their high fat content and partly to their high cellulose content, nuts are not easily digestible. However nuts eaten in a mixed diet are an extremely valuable source of protein. Peanuts for human consumption should be thoroughly dried and properly stored to avoid the growth of Aspergillus flavus which produces “aflatoxin”.

5. Fruits

Fruits are protective foods. They are invaluable in human nutrition because they are good sources of vitamins and minerals. One special feature which distinguishes fruits from other foods is that they can be eaten raw and fresh. This makes the vitamins and minerals present in fruit easily available.

Nutritive value

(1) Vitamins: Fruits are prized for their vitamins. Most fruits contain significant amounts of ascorbic acid. The orange, guava and the Indian gooseberry (amla) are particularly rich in ascorbic acid. One medium sized orange can provide enough juice to meet the daily requirement of ascorbic acid of an adult. Apart from ascorbic acid, several fruits contain good amounts of carotene. The papaya and mango are excellent sources of carotene. (2) Minerals: Fruits are good sources of minerals especially sodium and potassium. Some fruits like sitaphal (custard apple) are rich in calcium. Dried fruits like raisins, dates and apricots are good sources of calcium and iron. Fruits also contain a great variety of organic acids which are responsible for the sourness of unripe fruits. The intake of fruits leads to an alkaline urine. (3) Carbohydrates: Fruits in general have a low energy value but some fruits like banana and mango contain good amounts of carbohydrate and can act as good source of energy. Pectin, a kind of sugar, present in fruits like guavas is helpful in the preparation of fruit jellies. The fruit sugars are easily digestible and completely absorbed. The more ripe a fruit is, the higher its sugar content. (4) Cellulose: Fruits contain cellulose which assists in normal bowel movements.

Nutrition experts recommend a daily intake of 85 grams or more of fresh fruit for maintenance of good health. Fruits are costly and it may not be within the reach of all to afford them daily. If green leafy vegetables are included in the daily diet, the need for fruit as an essential item in the diet is much reduced. The aim in nutrition education should be to promote the intake of seasonal fruits which are cheaper and easily available. The costly fruits are not necessarily the best in respect of nutrients. The food values of some common fruits are as given in Table 20.

6. Animal foods

Foods of animal origin include meat, poultry, fish, eggs, milk and dairy products. They provide high quality protein (containing all the essential amino acids) and good amounts of fat, besides some vitamins and minerals. Vitamin B12 is one of the rare nutrients found only in animal foods. Since they are expensive, animal foods are consumed in small amounts in most countries.
amounts in most developing countries. Even small amounts of animal foods add considerably to the nutritive value of the diet. Among animal foods, cow's milk and hen's egg are perhaps nature's two most "nearly perfect" foods.

**Milk**

Milk is the best and most complete of all foods. It is secreted by the animals to serve as the sole and wholesome food for their suckling young ones. It is a fine blend of all the nutrients necessary for growth and development of the young ones. Thus milk is a good source of proteins, fats, sugars, vitamins and minerals.

(i) **Proteins** : The chief protein of milk is casein; it occurs in combination with calcium as calcium caseinogenate. The other proteins are lactalbumin and lactoglobulin. Animal milks contain nearly three times as much protein as human milk. Milk proteins contain all the essential amino acids. Human milk proteins contain greater amounts of tryptophan and sulphur-containing amino-acids (especially cystein) than the animal milk proteins. (ii) **Fat** : The fat content of milk varies from 3.4 per cent in human milk to 8.8 per cent in buffalo milk. Human milk contains a higher percentage of linoleic acid and oleic acid than animal milks. Milk fat is a good source of retinol and vitamin D. (iii) **Sugar** : The carbohydrate in all milks is lactose or milk sugar. It is found nowhere else in nature. It is less sweet than cane sugar and is readily fermented by lactic acid bacilli. Human milk contains more sugar than animal milks. (iv) ** Minerals** : Milk contains almost all known minerals needed by the body such as calcium, phosphorus, sodium, potassium, magnesium, cobalt, copper, iodine, etc. Milk is particularly rich in calcium; it is however a poor source of iron. (v) **Vitamins** : Milk is a good source of all vitamins except vitamin C.

Human and animal milks are as compared in Table 21, which illustrates that milk is to a great extent species-specific.

**Milk products**

Milk is consumed in a variety of forms — as whole milk, butter, ghee, cheese, dried and condensed milk, khoa, ice cream, etc. Milk from which fat has been removed, is known as "skimmed milk". It is devoid of fat and fat soluble vitamins, but a good source of milk protein (35 per cent) and calcium.

**Toned milk**

The term "toned" is an Indian coinage. It is a blend of natural milk and "made-up" milk. It contains 1 part of water, 1 part of natural milk and 1/8 part of skim milk powder. The mixture is stirred, pasteurized and supplied in bottles. Toned milk has a composition nearly equivalent to cow's milk. It is cheaper and yet a wholesome product.

**Vegetable milk**

Milk prepared from certain vegetable foods (viz. groundnut, soyabean) is termed "vegetable milk". It may be used as a substitute for animal milk. The Central Food Technological Research Institute, Mysore has perfected techniques for the preparation of vegetable milk (72).

**Egg**

Egg contains all the nutrients except carbohydrate and vitamin C. About 12 per cent of egg is made of shell, 58 per cent of egg white, and 30 per cent of egg yolk. An egg weighing 60 grams contains 6 g of protein, 6 g of fat, 30 mg of calcium and 1.5 mg of iron, and supplies about 70 kcal of energy. Egg proteins have all the nine essential amino acids needed by the body in right proportions. Nutritionists consider egg protein as the best among food proteins. In fact, egg protein is the standard against which the quality of other proteins is compared. Except for vitamin C, egg contains all the fat-soluble and water-soluble vitamins in appreciable amounts. Important minerals such as calcium, phosphorus, iron, zinc and other trace elements are present in the egg. Barring milk, no other food can supply such a diverse range of nutrients. Net protein utilization (NPU) which combines in a single value the biological value and digestibility, is 100 for egg compared to 80 for meat and 75 for milk. Raw egg white is not assimilated by the intestinal mucosa, therefore it must be cooked before consumption. Boiling destroys "avidin", a substance which prevents the body from obtaining biotin, one of the B-complex vitamins. Boiled egg is therefore nutritionally superior to raw egg. In recent years the cholesterol content of egg (250 mg/egg) has generated a sense of fear because of the risk of CHD. A reduction in intake of eggs is advised for those at risk of CHD. This should not distract others from eating eggs. Eggs or no eggs, cholesterol is formed in the body endogenously and is controlled by what is known as feedback mechanism.

**Fish**

Fish is nutritious food rich in proteins (15 to 25 per cent) with a good biological value and a satisfactory amino acid balance. The fat of fish is rich in unsaturated fatty acids and A and D vitamins. Fish liver oils are the richest source of vitamins A and D. Fish bones when eaten are an excellent source of calcium, phosphorus and fluorides. Fish are less rich in iron (0.7 to 3 mg per 100 g) than meat. Fresh water fish do not contain iodine, but sea fish do. Of all the sea foods, oysters and lobsters are the richest in iodine. There is a practical disadvantage to fish as a source of iodine, for milk is a good source of essential amino acids. Iron contained in meat (2 to 4 mg per 100 g) is more easily absorbed than iron in plants and this is another major quality of meat. In addition,
meat contains varying amounts of fat, which is composed of non-essential saturated fat. The energy provided by meat depends upon its fat content. Besides iron, meat provides minerals such as zinc and B-vitamins. It is poor in calcium (10 to 25 mg per 100 g) but rich in phosphorus. Liver is extremely rich in many nutrients.

Table 22 shows the nutritive value of meat, fish and eggs.

7. Fats and oils

Good cooking demands liberal use of oils and fats. Fats which are liquid at room temperature are called oils. Fats and oils are good sources of energy and fat-soluble vitamins. Fats of animal origin are poor sources of essential fatty acids. Those of vegetable origin are rich in poly-unsaturated fatty acids, excepting coconut and palm oils. The vegetable fats contain no vitamin A and D, except for red palm oil which is extremely rich in carotene. During the past 25 years, there has been a great increase in manufacture of vanaspati (hydrogenated fat) under various trade names. Margarine is made from vegetable oils and is fortified with vitamin A and D.

8. Sugar and Jaggery

These are carbohydrate foods. Sugar is produced from sugarcane in India, and from sugar beet elsewhere. Refined sugar is pure sucrose and contains no other nutrients. Jaggery is prepared from sugarcane in India and is consumed in place of sugar. It contains useful amounts of carotene and iron derived from cooking pans. Honey consists of about 75 per cent sugars, mostly fructose and glucose.

9. Condiments and spices

These include asafoetida, cardamom, chilies, garlic, cloves, ginger, mustard, pepper, tamarind, turmeric, etc. They are mainly used to enhance the palatability of foods and stimulate appetite. The essential oils present in them have carminative properties and may aid in digestion. Excessive consumption of condiments is associated with peptic ulcer.

10. Miscellaneous

Beverages: Diet includes beverages, and especially water which is essential to life. Beverages include drinks which are appreciated for their flavour or their stimulating properties. They may be classified as follows:

(i) Coffee, tea, cocoa.
(ii) Soft drinks: aerated water, lemonade, pepsi cola, fruit juices, etc.
(iii) Alcoholic beverages: wine, beer, whisky and traditional preparations. Alcoholic beverages are rich in calories.

Coffee, tea and cocoa

(a) Coffee: Coffee contains caffeine (0.6 to 2.0 per cent), volatile oils (caffeol) and tannic acid. Caffeine is a stimulant of the nervous system. When coffee seeds are roasted, tannin is destroyed, proteins are coagulated and the pleasant aroma is liberated.

(b) Tea: There are two main varieties of tea – the green and the black varieties. Green tea which is more astringent than the black variety is popular in China, Japan and Assam. The chemical composition of tea is as follows:

(i) caffeine: 2 to 6 per cent;
(ii) tannic acid: 5 to 12 per cent;
(iii) theophylline: traces; and
(iv) essential volatile oils: 5 per cent.

Tea is prepared by adding leaves to boiling water. When milk is added; the casein of milk combines with tannin and forms a harmless complex.

(c) Cocoa: Cocoa is obtained from cocoa beans. It is rich in fat, and contains theobromine which has stimulating properties. The composition of a cup of tea, coffee and cocoa containing the usual amount of sugar is given in Table 23. The nutritive value of a cup of tea or coffee is really due to its milk and sugar content.

Soft drinks

Some are carbonated (e.g., soda water incorporating carbon dioxide under high pressure) and others non-carbonated such as fruit juices. The principal ingredients of soft drinks are carbon dioxide, sugars, acids such as citric acid or tartaric acid, colouring and flavouring agents. Fruit beverages comprise fruit juices, squashes and cordials. Fruit squashes and cordials are diluted with water before consumption.

Alcoholic beverages

These are beer, whisky, rum, gin, arrack, etc. The alcoholic content of these beverages varies widely from 5 to 6 per cent in beers to 40 to 45 per cent in whisky, rum, gin and brandy. Alcohol supplies about 7 kcal per gram.

b. Vinegar

Natural vinegar is made from fermentation of fruits, malt and molasses. It contains a minimum of 3.7 per cent acetic acid. Synthetic vinegar should not be harmful if it is free from lead, copper, arsenic or mineral acids. Synthetic vinegar should be distinctly labelled “SYNTHETIC” according to Prevention of Food Adulteration Act rules.

NUTRITIONAL REQUIREMENTS

Basic concepts

The science of human nutrition is mainly concerned with defining the nutritional requirements for the promotion, protection and maintenance of health in all groups of the population. Such knowledge is necessary in order to assess the nutritional adequacy of diets for growth of infants,
children and adolescents, and for maintenance of health in adults of both sexes and during pregnancy and lactation in women (83). In this context, a variety of terms have been used to define the amount of nutrients needed by the body such as: optimum requirements, minimum requirements, recommended intakes or allowances, and safe level of intake. Of these, the term “recommended dietary intake or allowance” (RDA) has been widely accepted (1).

Recommended dietary allowance (RDA) : The average daily dietary nutrient intake level sufficient to meet the nutrient requirement of nearly all (97–98 per cent) healthy individuals in a particular life stage and gender group (9).

Adequate Intake : A recommended average daily intake level based on observed or experimentally determined approximations or estimates of nutrient intake by a group (or groups) of apparently healthy people, that are assumed to be adequate – used when an RDA cannot be determined. In the Indian context, this is referred to as “acceptable intake” (9).

Tolerable upper intake level (UL) : The highest average daily nutrient intake level that is likely to pose no risk of adverse health effects for almost all individuals in the general population. As intake increases above the UL, the potential risk of adverse effect increases (9).

Estimated average requirement (EAR) : The average daily nutrient intake level estimated to meet the requirement of half of the healthy individuals in a particular life stage and gender group (9).

The RDA is derived from (a) the individual variability; and (b) the nutrient bioavailability from the habitual diet.

Individual variability : Definition of RDA takes into account the variability that exist in the requirement of a given nutrient between individuals in a given population group. The distribution of nutrient requirement in a population group is considered normal when the RDA corresponds to a requirement, which covers most of the individuals (97.5 per cent) in a given population. This corresponds to mean + 2 SD. This is termed as a safe level of nutrient; the chances of individual having requirements either in excess or below the actual requirement of energy are not safe. In respect to other nutrients, the RDA is 25 per cent (+ 2 SD) higher than the mean requirement, 12.5 per cent being considered as the extent of individual variability in the requirement of all those nutrients (9).

Bioavailability : Bioavailability of a given nutrient from a diet, i.e., the release of the nutrient from the food, its absorption in the intestine and bioreponse have to be taken into account. It is the level of the nutrient that should be present in the diet to meet the requirement. The bioavailability factor is quite important in calcium, protein and trace elements like iron and zinc. In case of iron, the amount present in the diet is to be 20-30 times higher than the actual iron requirement to account for the low bioavailability of iron from a given diet, particularly a cereal-based diet.

RDA presents the level of the nutrient to be consumed daily to meet all the requirements of most of the individuals in a given population. However, it must be recognized that the RDA is not meant to be used as a standard to determine whether or not a given individual requirement has been met, since it is a level above the requirement of most individuals in a given population. RDA value of a nutrient is valid only when all other dietary nutrient intakes are satisfactory.

REFERENCE BODY WEIGHTS (9)

Age, gender and body weight largely determine the nutritional requirement of an individual. Body weights and heights of children reflect their state of health, nutrition and growth rate, while weight and heights of adults represent what can be attained by an individual with normal growth. Anthropometric measurements of infants and children of well-to-do families having access to good health care and no nutritional constraints are usually treated as reference values. The purpose of recommending nutrient requirements is to help attaining these anthropometric reference standards.

WHO standard weights and heights of infants and pre-school children

World Health Organization has recently published multi-centre growth reference standards for 0–60 month boys and girls, based on studies carried out among predominantly breast-fed children in six countries viz., USA, Brazil, Ghana, Norway, Oman and India. The median weights of infants and pre-school children (1–3 years) can be taken as reference values for Indian children.

Reference Indian adult man and woman

"Reference man" is aged between 18–29 years and weighs 60 kg with a height of 1.73 metre and a BMI of 20.3; is free from disease and physically fit for active work. On each working day, he is engaged in 8 hours of occupation which usually involves moderate activity; while when not at work he spends 8 hours in bed, 4–6 hours in sitting and moving about, 2 hours in walking and in active recreation or household duties.

"Reference woman" is aged between 18–29 years, non-pregnant non-lactating (NPNL) and weighs 55 kg with a height of 1.61 metre and a BMI of 21.2, is free from disease and physically fit for active work. On each working day she is engaged in 8 hours of occupation, which usually involves moderate activity, while when not at work she spends 8 hours in bed, 4–6 hours in sitting and moving about, 2 hours in walking and in active recreation or household duties.

Infants

The average of birth weight and body weight at 6 months is used for computing the reference body weight for infants 0–6 months of age. For 6–12 months, an average of body weight at 6 months and at 12 months is taken for computation.

Children

For children 1–3 years of age, an average of body weight at 18 months, 30 months, 42 months of WHO median weight is taken (as mentioned above).

The reference body weight for children of 4–6 years are obtained by averaging the body weight of 4+, 5+ and 6+ years. Similarly for other age groups also the reference body weights were obtained from the 95th centile value of body weights of rural India.

Adults

The average of values for age category of 18–19, 20–24, and 25–29 years was used for computing the reference weights for adult man and woman.
Energy

Energy is a prime requisite for body function and growth. When a child's intake of food falls below a standard reference, growth slows, and if low levels of intake persist, adult stature will be reduced. Similarly, if adults fail to meet their food requirements they lose weight. This may lead to reduced ability to work, to resist infection, and weakened will to enjoy the normal satisfaction of life. This underlines the need for an adequate intake of food which is the source of all energy.

Measurement of energy

The energy value of foods has long been expressed in terms of the kilocalorie (kcal). The kilocalorie is generally expressed as "Calorie"—written with a capital "C" (74). This has been replaced by the "joule" expressed as J, which has been accepted internationally. These units are defined as follows:

Joule, a physical unit of energy, is defined as the energy required to move 1 kg of mass by 1 metre by a force of 1 Newton acting on it (One Newton is the force needed to accelerate one kg mass by 1 metre per sec²).

Kilocalorie (kcal) is defined as the heat required to raise the temperature of one kg of water by 1°C from 14.5°C to 15.5°C. The unit kcal is still popularly used.

The relationship between the two units of energy is as follows:

1 kcal = 4.184 KJ (Kilo Joule)
1 KJ = 0.239 kcal
1000 kcal = 4184 KJ = 4.18 MJ (Mega Joule)
1 MJ = 239 kcal

Reference man and woman

Energy intake recommendations are formulated for a "reference man" and a "reference woman" whose profiles are described, and then necessary adjustments are made for subjects who deviate from the standard reference. This procedure was first devised by the FAO Committee on calorie requirements in 1950 (75) and has been in use ever since.

Energy requirements

The energy requirement of a person is defined as the level of energy intake from food that balances energy expenditure, when the individual has a body size and composition and level of physical activity, consistent with long-term good health, also allowing for maintenance of economically essential and socially desirable activity. In children and pregnant and lactating women, it includes the energy needs associated with the deposition of tissues or secretion of milk at rates consistent with good health (9).

The two standard deviation value is not added to the average requirement. This is because the energy intake and expenditure of an individual are finely balanced, and any surplus energy consumption will be stored as fat and a continuous excess of intake will lead to obesity (9). Adults and even growing children are known to adapt either intake to suit their output, or output to suit intake over a very wide range. We do not have a proper understanding of the lower limit of adaption.

Broadly, the total energy requirement of an individual is made up of three components:

(a) energy required for basal metabolism. This is about 1 kcal/hour for every kg of body weight for an adult;
(b) energy required for daily activities such as walking, sitting, standing, dressing, climbing stairs, etc; and
(c) energy expenditure for occupational work. This is further classified as light work (an office clerk), moderate work and heavy work (manual physical labour).

The first component is nearly the same for all individuals. It is the latter two components that vary depending upon the type of activities. Procedures for calculating total energy expenditure are given in the WHO Expert Committee Report on Energy and Protein Requirements (6).

Factors affecting energy requirements

Energy requirements vary from one person to another depending upon inter-related variables acting in a complex way, such as age, sex, working condition, body composition, physical activity, physiological state etc. All these factors lead to differences in food intake.

Energy requirements have been laid down by various expert groups of FAO and WHO (6, 38, 76). It has become customary for countries to lay down their own standards. Thus there are British standards, American standards, Canadian standards, etc. The standards in India are those recommended by the Indian Council of Medical Research which are set out in Table 24. These standards are revised from time to time in the light of newer knowledge.

Vulnerable groups

(a) Pregnant and lactating mothers: The energy requirements of women are increased by pregnancy (+350 kcal daily throughout pregnancy) and lactation (+600 kcal daily during the first 6 months, and +520 kcals daily during the next 6 months) over and above their normal requirements. This is to provide for the extra energy needs associated with the deposition of tissues or the secretion of milk at rates consistent with good health (6).

(b) Children: Because of their rapid growth rate, young children require proportionately more energy for each kilogram of body weight than adults (see Table 29).

A problem that arises is in recommending intakes in communities where a large number of children are underweight because of malnutrition. In order to provide for "catch-up growth" during childhood, intakes should be based on age rather than weight where practical (77). The ICNR standards are based on age, and not on body weight (except during the first year of life).

Children above the age of 13 years need as much energy as adults. This is because they show a good deal of physical activity, almost equal to hard work by adults. This is also the age when puberty sets in and there is a spurt in growth and an increase in metabolic rate. This fact should be borne in mind when planning dietaries for children.

(c) Adults: The energy requirements decrease with age because of a fall in BMR and a decrease in physical activity in most persons. In general, there is a 2 per cent decline of resting metabolism for each decade for adults (31). The FAO/WHO committee suggested that after the age of 40 years, requirements should be reduced by 5 per cent per each decade until the age of 60, and by 10 per cent for each decade thereafter (76).

- a Rounded off to the nearest 10 kcal/day.
- b GWG = Gestational weight gain. Energy need in pregnancy should be adjusted for actual body weight, observed weight gain, and activity pattern for the population.
- c WG = Gestational weight gain remaining after delivery.

Note: The current estimate of energy requirement of infants is 11-20 per cent lower than the 1988 estimates.

Source: (9)

**Source of energy**

The main source of energy in Indian diets, which are predominantly plant food based, are carbohydrate, fat, protein and dietary fibre. They supply energy at the following rates:

- **Protein** - 4 kcal/g
- **Fat** - 9 kcal/g
- **Carbohydrate** - 4 kcal/g
- **Dietary fibre** - 2 kcal/g

Dietary fibre forms an indigestible and important component of plant food and was never earlier considered as source of energy. These dietary fibres (soluble and insoluble) undergo fermentation in the colon and yield short chain fatty acids, such as butyric, propionic and acetic acids which are utilized as a source of energy by the colon cells and by the liver. Hence they are known to yield energy from fermentable fibre and no energy from non-fermentable fibre. In conventional foods, 70 per cent of fibre is fermentable. In general, energy conversion factor for fibre is taken as 2.0 kcal/g. Hitherto, dietary fibre was not determined directly as a source of energy and there is a need to recalculate energy yield of various foods on the basis of their revised content of carbohydrates, proteins, fat and dietary fibre (9).

The main source of energy in diets is carbohydrates derived largely from cereals. These cereals constitute about 80 per cent of our diet and provide 50-80 per cent of daily energy intake. However, energy contribution from diets varies very widely. Those belonging to low income group have only 5 per cent fat in their diet, whereas affluent families derive as high as 30 per cent of their dietary energy from fat. Most families derive 10-12 per cent of energy from proteins (9).

**Protein**

Protein requirements vary from individual to individual. Apart from age, sex and other physiological variables, factors like infection, worm infestation, emotional disturbances and stress situations can affect a person's protein requirement.

**Assessment of protein**

(a) **PROTEIN QUALITY**

The quality of a protein is assessed by comparison to the "reference protein" which is usually egg protein. Two methods of assessment of protein quality needs mention:

(i) **Amino acid score**: It is a measure of the concentration of each essential amino acid in the test protein expressed as a percentage of that amino acid in the reference protein.

\[
\text{Amino acid score} = \frac{\text{mg of the same amino acid}}{\text{mg of amino acid per g of test protein}} \times 100
\]

The amino acid (or chemical) score is somewhere between 50 and 60 for starches, and 70 and 80 for animal foods (69).

(ii) **Net protein utilization (NPU)**: It is a product of digestibility coefficient and biological value divided by 100 (8). The NPU gives a more complete expression of protein quality than the amino acid score. It is a biological method that requires special laboratory facilities.

\[
\text{NPU} = \frac{\text{Nitrogen retained by the body}}{\text{Nitrogen intake}} \times 100
\]

In calculating protein quality, 1 gram of protein is assumed to be equivalent to 6.25 g of N.

The protein requirement varies with the NPU of dietary protein. If the NPU is low, the protein requirement is high and vice versa. The NPU of the protein of Indian diets varies between 50 and 80.

(b) **PROTEIN QUANTITY**

The protein content of many Indian foods has been determined and published in food composition tables. One way of evaluating foods as source of protein is to determine what per cent of their energy value is supplied by their protein content. This is known as **Protein-Energy Ratio** (PE ratio or percentage).

\[
\text{PE per cent} = \frac{\text{Energy from protein}}{\text{Total energy in diet}} \times 100
\]

This concept is useful because in many population groups adequate diet is not consumed to meet energy needs, resulting in energy deficits. The ratio of protein requirement,
expressed as the ratio of protein calories to the energy requirement is as given in Table 25.

</table>

If the PE is less than 4 per cent, the subject will be unable to eat enough to satisfy protein requirements. It is recommended that protein should account for approximately 10–12 per cent of the total daily energy intake.

**Dietary intakes**

It is customary to express requirement in terms of grams per kg of body weight. This principle applies to all age groups, although absolute additions in units of grams of protein per day are made for pregnancy and lactation.

The ICMR Expert Group (9) suggested an intake of one gram of protein per kg of body weight for adult males and females, assuming a NPU of 65 for the dietary protein. Table 29 gives the protein intakes for individuals of different ages and physiological states.

**Vulnerable groups**

The protein requirements of women are increased during pregnancy. For 10 kg gestational weight gain the requirement increases by 1, 7 and 23 g/day in 1st, 2nd and 3rd trimesters respectively; and during lactation by about 13 g per day (during 0 to 6 months), over and above their normal requirements.

Young children (0 to 6 years) require proportionately more protein for each kilogram of body weight than adults. They are more vulnerable to malnutrition.

The ICMR Expert Group (9) has not made any recommendations for the elderly. It seems reasonable to assume that the requirement of the aged are not less than that for young adults, because it is an accepted fact that protein utilization is less efficient in the elderly (6).

All estimates of protein requirement are valid only when the energy requirements are fully met. If the total energy intake is inadequate some dietary protein will be diverted to provide energy. It is now accepted that there are no body protein stores which can be filled up by a high protein intake.

At present there is no evidence that higher intakes of protein confer greater benefit, although the possibility cannot be ruled out. Most people, if they can, apparently choose to eat more protein than the physiological requirement. The question remains whether high protein intakes, far from being beneficial, may actually be harmful (7).

**Amino acid requirements**

The protein intake must also satisfy the need for essential amino acids. The 2007 WHO Expert Committee Report on Energy and Protein Requirements gives current estimates of amino acid requirements (in mg/kg per day) for adults. These are reproduced in Table 27.

</tr>
</tbody>
</table>

Source: (9)

New tissues cannot be formed unless all the essential amino acids are present in the diet. The requirement of EAA decreases sharply as one advances in age. The quality of the diet is far more critical for the infant than for the adult.

**FAT**

The daily requirement of fat is not known with certainty. During infancy, fats contribute to a little over 50 per cent of the total energy intake. This scales down to about 20 per cent in adulthood. The ICMR Expert Group (2010) has recommended an intake of 20 per cent of the total energy intake as fat, of which at least 50 per cent of fat intake should consist of
vegetable oils rich in essential fatty acids. The requirement of essential fatty acids ranges from 3 per cent energy intake to 5.7 per cent of energy intake in young children.

Suggested levels of fat intake are as given in Table 28.

</table>

**CARBOHYDRATE**

The recommended intake of carbohydrate in balanced diets is placed so as to contribute between 50 to 80 per cent of total energy intake. Most Indian diets contain amounts more than this, providing as much as 90 per cent of total energy intake in some cases, which makes the diet imbalanced. This needs to be corrected through nutrition education.

The recommended dietary allowances for energy, protein, fat and minerals is summarized in Table 29.

**OTHER RECOMMENDED INTAKES**

(a) *Fat soluble vitamins*

The daily requirement of vitamins A is given in Table 30. The recommended dietary allowance of vitamin E is placed at 10 mg of alpha tocopherol equivalents for adult males and 8 mg for adult females.

(b) *Water soluble vitamins*

The recommended intakes are given in Table 30. The requirements of thiamine, riboflavin and niacin are closely related to energy intake and utilization, and are stated in terms of 1000 kcal intake of energy as below:

- Thiamine: 0.5 mg/1000 kcal
- Riboflavin: 0.6 mg/1000 kcal
- Niacin: 6.0 mg/1000 kcal

(c) *Minerals*

The recommended intakes of important minerals are as given in Table 29.

Source: (9)
All nutritional requirements are interrelated. For example, there is a close interrelationship between the energy and protein requirements, between requirements for phosphorus, calcium and vitamin D, between fats and vitamins, and between carbohydrates and vitamins.

It has been said that food is not only a collection of nutrients open to statistical or dietary study, but also simultaneously a system of communication, a protocol for customs, situations and behaviour.

BALANCED DIET

A diet may be defined as the kinds of food on which a person or group lives. A balanced diet is defined as one which contains a variety of foods in such quantities and proportions that the need for energy, amino acids, vitamins, minerals, fats, carbohydrate and other nutrients is adequately met for maintaining health, vitality and general well-being and also makes a small provision for extra nutrients to withstand short duration of leanness (69). A balanced diet has become an accepted means to safeguard a population from nutritional deficiencies (79).

In constructing balanced diet, the following principles should be borne in mind: (a) First and foremost, the daily requirement of protein should be met. This amounts to 10-15 per cent of the daily energy intake. (b) Next comes the fat requirement, which should be limited to 15-30 per cent of the daily energy intake (c) Carbohydrates rich in natural fibre should constitute the remaining food energy. The requirements of micronutrients (Table 29 and 30) should be met.

The dietary pattern varies widely in different parts of the world. It is generally developed around the kinds of food produced (or imported) depending upon the climatic conditions of the region, economic capacity, region, customs, taboos, tastes and habits of the people. Balanced diets formulated by the Indian Council of Medical Research are given in Annexure II at the end of this chapter.

A nutritional education guide "The Food Guide Pyramid" emphasizes foods from the five major food groups shown in the three lower sections of the Pyramid (Fig. 1). Each of these food groups provides some, but not all, of the nutrients required. Foods in one group can’t replace those in another. No one of these major food groups is more important than another – for good health, one needs them all.

DIETARY GOALS

All countries should develop a national nutrition and food policy setting out "dietary goals" for achievement (72). The dietary goals ("prudent diet") recommended by the various Expert Committees of WHO (15,79) are as below:

(a) dietary fat should be limited to approximately 15-30 per cent of total daily intake;
(b) saturated fats should contribute no more than 10 per cent of the total energy intake; unsaturated vegetable oils should be substituted for the remaining fat requirement;
(c) excessive consumption of refined carbohydrate should be avoided; some amount of carbohydrate rich in natural fibre should be taken;
(d) sources rich in energy such as fats and alcohol should be restricted;
(e) salt intake should be reduced to an average of not more than 5 g. per day; (salt intake is more in tropical countries. In India it averages 15 g. per day);
NUTRITIONAL PROBLEMS IN PUBLIC HEALTH

There are many nutritional problems which affect vast segments of our population. The major ones which deserve special mention are highlighted:

1. Low birth weight

Low birth weight (i.e., birth weight less than 2500 g) is a major public health problem in many developing countries. According to Rapid Survey Report on Children 2014, about 18.6 per cent of babies born in India are LBW (81) as compared to 4 per cent in some developed countries. In countries where the proportion of LBW is high, the majority are suffering from postnatal growth retardation. In countries where the proportion of LBW infants is low, most of them are preterm. Although we do not know all the causes of LBW, maternal malnutrition and anaemia appear to be significant risk factors in its occurrence. Among the other causes of LBW are hard physical labour during pregnancy, and illnesses especially infections. Short maternal stature, very young age, high parity, smoking, close birth intervals are all associated factors. All these factors are interrelated (82).

Since the problem is multifactorial, there is no universal solution. Interventions have to be cause-specific. This matter has already been discussed in Chapter 10.

2. Under nutrition

Undernutrition is identified as a major health and nutrition problem in India. It is not only an important cause of childhood morbidity and mortality, but leads also to permanent impairment of physical and possibly, of mental growth of those who survive (9).

The nutrition problem frequently encountered, particularly among the rural poor and urban slums in India are protein-energy malnutrition and micronutrient deficiencies. The term undernutrition encompasses stunting (chronic malnutrition), wasting (acute malnutrition) and underweight.

Persistent undernutrition through the growing phase of childhood leads to short stature in adults. About 33 per cent of adult men and 36 per cent of women have Body Mass Index (BMI) below 18.5, which indicates chronic energy deficiency. In case of tribal adults 40 per cent of men and 49 per cent of women are below 18.5 BMI (85).

Children are more vulnerable to the effects of undernutrition. According to Rapid Survey on Children (RSoC) 2014, about 18.5 per cent of children are born with low birth weight, 29.4 per cent are underweight (weight for age < 5 years of age), 38.7 per cent are stunted (height for age < 5 years), 15.1 per cent are wasted (weight for height) and <1 per cent children under 5 years are having kwashihork or Marasmus.

In the 1970s, it was widely held that PEM was due to protein deficiency. Over the years, the concept of "protein gap" has given place to the concept of "food gap". That is, PEM is primarily due to (a) an inadequate intake of food...
(food gap) both in quantity and quality, and (b) infections, notably diarrhoea, respiratory infections, measles and intestinal worms which increase requirements for calories, protein and other nutrients, while decreasing their absorption and utilization. It is a vicious circle – infection contributing to malnutrition and malnutrition contributing to infection, both acting synergistically (Fig. 2).

There are numerous other contributory factors in the web of causation, viz. poor environmental conditions, large family size, poor maternal health, failure of lactation, premature termination of breast-feeding, and adverse cultural practices relating to child rearing and weaning such as the use of over-diluted cow’s milk and discarding cooking water from cereals and delayed supplementary feeding. Malnutrition is self-perpetuating. A child’s nutritional status at any point of time depends on his or her past nutritional history, which may particularly account for the present status. To some extent, this nutritional history is linked to the mother’s health and nutritional status. This in turn has been influenced by her living conditions and nutritional history during her own childhood (Fig. 3).

Measurement of Undernutrition

In children, undernutrition is synonymous with growth failure - undernourished children are shorter and lighter than they should be for their age/height. To get a measure of malnutrition in a population, young children are weighed and/or their height is measured and the results compared to those of a ‘reference population’ known to have grown well. Measuring weight and height is the most common way of assessing malnutrition in a given population. Such use of measurements of dimensions of the human body is known as anthropometry.

Anthropometry is a widely used, inexpensive and non-invasive measure of the general nutritional status of an individual or a population group. The three commonly used anthropometric indices are:

- Weight-for-Age (WFA).
- Length-for-Age or Height-For-Age (HFA).
- Weight-for-Length or Weight-for-Height (WFH).

Types of Undernutrition (73)

The three indices – weight-for-age, height/length-for-age, weight-for-height/length are used to identify three nutrition conditions: underweight, stunting and wasting, respectively. Each of the three nutrition indicators is expressed in standard deviation units (Z-scores) from the median of the reference population based on which undernutrition may be further classified as moderate or severe.

Underweight

Underweight, based on weight-for-age, is a composite measure of stunting and wasting, and is recommended as the indicator to assess changes in the magnitude of malnutrition over time. This condition can result from either chronic or acute malnutrition, or both. Underweight is often used as a basic indicator of the status of a population’s health as weight is easy to measure. Evidence has shown that the mortality risk of children who are even mildly underweight is increased, and severely underweight children are at even greater risk.

An underweight child has a weight-for-age Z-score that is at least two standard deviations (-2SD) below the median of the WHO Child Growth Standards.

Stunting

Failure to achieve expected height/length as compared to healthy, well-nourished children of the same age is a sign of stunting. Stunting is an indicator of linear growth retardation that results from failure to receive adequate nutrition over a long period or recurrent adequate nutrition over a long period or recurrent infections. It may be exacerbated by recurrent and chronic illness. It is an indicator of past growth failure. It is associated with a number of long-term factors including chronic insufficient nutrient intake, frequent infection, sustained inappropriate feeding practices and poverty. Stunting often results in delayed psycho-social and cognitive development and poor school performance.

A stunted child has a height-for-age Z-score that is at least two standard deviations (-2SD) below the median for the WHO Child Growth Standards.

Wasting

Wasting represents a recent failure to receive adequate...
nutrition and may be affected by recent episodes of diarrhoea and other acute illnesses. Wasting indicates current or acute malnutrition resulting from failure to gain weight or actual weight loss. Causes include inadequate food intake, incorrect feeding practices, disease, and infection or, more frequently, a combination of these factors. Wasting in individual children and population groups can change rapidly and shows marked seasonal patterns associated with changes in food availability or disease prevalence to which it is very sensitive.

A wasted child has a weight-for-height Z-score that is at least two standard deviations (−2SD) below the median for the WHO Child Growth Standards.

Severe Acute Malnutrition (SAM)

Severe acute malnutrition is defined by very low weight-for-height/length (Z-score below −3SD of the median WHO child growth standards), a mid-upper arm circumference <115 mm, or by the presence of nutritional oedema.

SAM increases significantly the risk of death in children under five years of age. It can be an indirect cause of child death by increasing the case fatality rate in children suffering from common illnesses such as diarrhoea and pneumonia. Children who are severely wasted are 9 times likely to die than well-nourished children.

Kwashiorkor and Marasmus

Kwashiorkor and marasmus are the two different forms of protein and energy malnutrition. The main cause of this form of malnutrition is inadequate protein intake and low concentration of essential amino acids. Kwashiorkor is a severe form of undernutrition, which develops in individuals on diets with a low protein-energy ratio. The main symptoms of Kwashiorkor are oedema, wasting, liver enlargement, hypoalbuminaemia, steatosis and the possible depigmentation of skin and hair.

Marasmus is the other form of malnutrition, which is caused by inadequate intake of both protein and energy. It is a form of severe cachexia with weight loss as a result of wasting in infancy and childhood. The main symptoms of marasmus are severe wasting, with little or no oedema, minimal subcutaneous fat, severe muscle wasting and non-normal serum albumin levels.

Early detection of PEM

The first indicator of PEM is under-weight for age. The most practical method to detect this, which can be employed even by field health workers, is to maintain growth charts. These charts indicate at a glance whether the child is gaining or losing weight.

Arm circumference: Arm circumference yields a relatively reliable estimation of the body’s muscle mass, the reduction of which is one of the most striking mechanisms by which the body adjusts to inadequate energy intakes. Arm circumference cannot be used before the age of one year; between ages one and five years, it hardly varies. An arm circumference exceeding 13.5 cm is a sign of a satisfactory nutritional status, between 12.5 and 13.5 cm it indicates mild–moderate malnutrition and below 12.5 cm, severe malnutrition (68).

Preventive measures

There is no simple solution to the problem of PEM. Many types of actions are necessary. The following is adapted from the 8th FAO/WHO Expert Committee on Nutrition (1) for the prevention of PEM in the community:

(a) Health promotion:
1. Measures directed to pregnant and lactating women (education, distribution of supplements);
2. Promotion of breast-feeding;
3. Development of low cost weaning foods: the child should be made to eat more food at frequent intervals;
4. Measures to improve family diet;
5. Nutrition education – Promotion of correct feeding practices;
6. Home economics;
7. Family planning and spacing of births; and
8. Family environment.

(b) Specific protection:
1. The child’s diet must contain protein and energy rich foods. Milk, eggs, fresh fruits should be given if possible:
2. Immunization; and
3. Food fortification.

(c) Early diagnosis and treatment:
1. Periodic surveillance;
2. Early diagnosis of any lag in growth;
3. Early diagnosis and treatment of infections and diarrhoea;
4. Development of programmes for early rehydration of children with diarrhoea;
5. Development of supplementary feeding programmes during epidemics; and

(d) Rehabilitation:
1. Nutritional rehabilitation services;
2. Hospital treatment; and
3. Follow-up care.

3. Xerophthalmia

Xerophthalmia (dry eye) refers to all the ocular manifestations of vitamin A deficiency in man. It is the most widespread and serious nutritional disorder leading to blindness (87) particularly in South-East Asia.

Xerophthalmia is most common in children aged 1–3 years, and is often related to weaning. The younger the child, the more severe the disease. It is often associated with PEM. Mortality is often high in this age group (21). The victims belong to the poorest families. Associated risk factors include ignorance, faulty feeding practices and infections particularly diarrhoea and measles which often precipitate xerophthalmia. In some countries, “epidemics” of xerophthalmia have occurred in association with food donation programmes involving skimmed milk, which is totally devoid of vitamin A (88).

The States badly affected are the southern and eastern States of India notably Andhra, Tamil Nadu, Karnataka, Bihar and West Bengal. These are predominantly rice-eating States and rice is devoid of carotene. The North Indian States have relatively few cases of xerophthalmia (89).

Prevention and control

Prevention and control of xerophthalmia must be an
integral part of primary health care. An overall strategy can be defined, according to WHO, in terms of short-term, medium-term and long-term action (24).

(a) Short-term action: A short-term preventive approach that has already demonstrated its efficacy is the administration of large doses of vitamin A orally, in recommended doses to vulnerable groups, on a periodic basis. This can be organized quickly and with a minimum of infrastructure.

(b) Medium-term action: An approach widely used to promote regular and adequate intake of vitamin A is fortification of certain foods with vitamin A. Addition of vitamin A to dalda in India is a typical example. Many other foods have also been considered for vitamin A fortification, viz., sugar, salt, tea, margarine and dried skimmed milk. Fortifying an appropriate food with vitamin A is a complex process. The greatest challenge to successful fortification programmes is choosing a food that is likely to be consumed in sufficient quantities by groups at risk (90).

(c) Long-term action: These are measures aimed at reduction or elimination of factors contributing to ocular disease, e.g., persuading people in general, and mothers in particular, to consume generously dark green leafy vegetables or other vitamin A rich foods; promotion of breast-feeding for as long as possible; improvements in environmental health such as ensuring safe and adequate water supply and construction and maintenance of sanitary latrines to safeguard against diarrhoea; immunization against infectious diseases such as measles, prompt treatment of diarrhoea and other associated infections; better feeding of infants and young children; improved health services for mothers and children; social and health education. All these are components of primary health care.

Vitamin A deficiency in India (VAD) (91)

VAD has been recognized as a major controllable public health and nutritional problem in India. An estimated 5.7 per cent children in India suffer from eye signs of VAD. Recent evidence suggests that even mild VAD probably increases morbidity and mortality in children, emphasizing the public health importance of this disorder. VAD is one of the major deficiencies among lower income strata population in India.

Though the prevalence of severe forms of VAD such as corneal ulcers/softening of cornea i.e. keratomalacia has in general become rare, Bitot spots were present in varying magnitudes in different parts of the country as reported by National Nutritional Monitoring Bureau in 2005-06. The prevalence was higher than WHO cut-off level of 0.8-1.0 per cent, indicating the public health significance of the problem of VAD (85). There is huge inter-state variation in the prevalence of VAD among children. It is also a matter of concern that only 21 per cent of children of age 12 to 35 months receive a vitamin A dose. Less than 10 per cent coverage was reported in Nagaland, Uttar Pradesh reported 7.3 per cent coverage. Only states such as Tamil Nadu (37.2 per cent), Goa (37.3 per cent), Kerala (38.2 per cent) and West Bengal (41.2 per cent) have better coverage, though it is still low.

In India, in 1970 a national programme for prevention of nutritional blindness was initiated to fight this deficiency. The beneficiaries of this programme were pre-school children (1-5 years). The programme was modified in 1992 to cover children in age group of nine months to three years only. Since Tenth Five Year Plan vitamin A supplementation exists as an integral component of RCH programme which is now a part of NRHM. The guidelines issued in November 2006 cover children up to 5 years of age.

The programme focuses on (92): (a) Promoting consumption of vitamin A rich foods by pregnant and lactating women and by children under-five years of age and appropriate breast-feeding; (b) Administration of massive dose of vitamin A up to five years. First dose of 100,000 IU with measles vaccination at nine months and subsequent doses of 200,000 IU each, every six months up to the age 5 years; (c) For sick children – all children with xerophthalmia to be treated at health facilities; all children suffering from measles to be given one dose of vitamin A if they have not received it in the previous one month; all cases of severe malnutrition to be given one additional dose of vitamin A (92).

4. Nutritional anaemia

Nutritional anaemia is a disease syndrome caused by malnutrition in its widest sense (54). It has been defined by WHO as "a condition in which the haemoglobin content of blood is lower than normal as a result of a deficiency of one or more essential nutrients, regardless of the cause of such deficiency" (52). Anaemia is established if the haemoglobin is below the cut-off points recommended by WHO (Table 13). By far the most frequent cause of nutritional anaemia is iron deficiency, and less frequently folate or vitamin B12 (49).

The problem

WORLD

Nutritional anaemia is a worldwide problem with the highest prevalence in developing countries. It is found especially among women of child-bearing age, young children and during pregnancy and lactation. It is estimated to affect nearly two-thirds of pregnant and one-half of non-pregnant women in developing countries (93). The populations of developed countries are not by any means completely free of anaemia, and a significant percentage of women of child-bearing age (estimated between 4 and 12 per cent) suffer from anaemia (94).

INDIA

Iron deficiency anaemia is the most widespread micronutrient deficiency affecting all age groups irrespective of gender, cast, creed and religion. In India, this silent emergency is rampant among women belonging to reproductive age group (15–49 years), children (6–35 months) and low socio-economic strata of the population. Overall, 72.7 per cent of children up to the age 3 years in urban areas and 81.2 per cent in rural areas are anaemic.

While analyzing the data for states with anaemia level of 70% among children, it was found that, except for Punjab, all other states had more than 50% prevalence of anaemia among pregnant women. This again reiterates the strong relationship between anaemia levels of mothers and children. Also, the overall prevalence has increased from 74.2% (1998–99) to 79.2% (2005–06). Nagaland had the lowest prevalence (44.3%), Goa was next (49.3%) followed by Mizoram (51.7%). Bihar had the highest prevalence (87.6%) followed closely by Rajasthan (85.1%), and Karnataka (82.7%). Moderate and severe anaemia is seen even among the educated families both in urban and rural areas. There are inter-state differences in prevalence of anaemia that are perhaps attributable partly to differences in dietary intake and partly to access to health care (91).
As per District Level Health Survey (DLHS) (2002–04), prevalence of anaemia in adolescent girls is very high (72.6%) in India, with prevalence of severe anaemia among them much higher (21.1%) than that in preschool children (2.1%). In adolescent girls, educational or economic status does not seem to make much of a difference in terms of prevalence of anaemia. Prevention, detection, or management of anaemia in adolescent girls has till now not received much attention. In view of the high prevalence of moderate and severe anaemia in this group and the fact that many of them get married early, conceive, and face the problems associated with anaemia in pregnancy, it is imperative to screen them for anaemia and treat them.

Iron deficiency can arise either due to inadequate intake or poor bioavailability of dietary iron or due to excessive losses of iron from the body. Although most habitual diets contain seemingly adequate amounts of iron, only a small amount (less than 5 per cent) is absorbed (96). This poor bio-availability is considered to be a major reason for the widespread iron deficiency (95). Women lose a considerable amount of iron especially during menstruation. Some of the other factors leading to anaemia are malaria and hookworm infestations. In addition mothers who have born children at close intervals become anaemic due to the additional demands of the rapid pregnancies and the loss of blood in each delivery.

Megaloblastic anaemia is not encountered frequently in general population, but it occurs occasionally in pregnant women from poor income groups. It is possible that the widespread iron deficiency (microcytic anaemia) could mask megaloblastic anaemia. In a recent study, sub-clinical folate deficiency was found to be about 30 per cent in pregnant women from rural North India. A high level of sub-clinical folate deficiency was also reported in semi-urban school children. There are some sporadic reports indicating its prevalence in adults (9).

Detrimental effects

The detrimental effects of anaemia can be seen in three important areas (49): (a) Pregnancy: Anaemia increases the risk of maternal and foetal mortality and morbidity. In India, 19 per cent of maternal deaths were found to be due to anaemia (54). Conditions such as abortions, premature births, postpartum haemorrhage and low birth weight were especially associated with low haemoglobin levels in pregnancy. (b) Infection: Anaemia can be caused or aggravated by parasitic diseases, e.g., malaria, intestinal parasites. Further, iron deficiency may impair cellular responses and immune functions and increase susceptibility to infection (c) Work capacity: Anaemia (even when mild) causes a significant impairment of maximal work capacity. The more severe the anaemia, the greater the reduction in work performance, and thereby productivity. This has great significance on the economy of the country.

Interventions

An estimation of haemoglobin should be done to assess the degree of anaemia. If the anaemia is “Severe”, less than 10 g/dl high doses of iron or blood transfusion may be necessary. If haemoglobin is between 10–12 g/dl, the other interventions are:

1. Iron and folic acid supplementation

In order to prevent nutritional anaemia among mothers and children, the Government of India sponsored a National Nutritional Anaemia Prophylaxis Programme during the Fourth Five Year Plan. The Programme is based on daily supplementation with iron and folic acid tablets to prevent mild and moderate cases of anaemia. The beneficiaries are “at risk” groups viz pregnant women, lactating mothers and children under 12 years.

Eligibility criteria (97): These are determined by the haemoglobin levels of the patients. If the haemoglobin is between 10 and 12, daily supplement with iron and folic acid tablets is advised; if it is less than 10 g, the patient is referred to the nearest primary health centre.

Dosage: (a) MOTHERS: One tablet of iron and folic acid containing 100 mg of elemental iron (300 mg of ferrous sulphate) and 0.5 mg of folic acid should be given daily. The daily administration should be continued until 2 to 3 months after haemoglobin level has returned to normal so that iron stores are replenished. It is necessary that estimation of haemoglobin is repeated at 3–4 month intervals. The exact period of supplementation will depend upon the progress of the beneficiary. (b) CHILDREN: If anaemia is suspected, a screening test for anaemia may be done on infants at 6 months, and 1 and 2 years of age. One tablet of iron and folic acid containing 20 mg of elemental iron (60 mg of ferrous sulphate) and 0.1 mg of folic acid should be given daily for 100 days. For children 6–60 months, ferrous sulphate and folic acid is to be provided in a liquid formulation. For safety sake, the liquid formulation should be dispensed in bottles so designed that only 1 ml can be dispensed each time. School children, 6 to 10 year old and adolescents are also to be included in the national programme. Children 6–10 years of age are to be provided 30 mg., elemental iron and 250 mcg. folic acid per day for 100 days. Adolescents are given the same dosage and duration as adults (92).

2. Iron fortification

The WHO experts (49) did not recommend iron fortification strategy for control of anaemia in regions where its prevalence is high. However, studies in India at the National Institute of Nutrition, Hyderabad showed that simple addition of ferric ortho-phosphate or ferrous sulphate was enough to fortify salt with iron (98). When consumed over a period of 12–18 months, iron fortified salt was found to reduce prevalence of anaemia significantly. Fortification of salt with iron has been accepted by the Government of India as a public health approach to reduce prevalence of anaemia. Commercial production of iron fortified salt was started in 1985 (98).

Iron fortification has many advantages over iron supplementation. As salt is a universally consumed dietary item, all segments of the population stand to benefit. No special delivery systems are required (53).

3. Other strategies

There are other strategies such as changing dietary habits, control of parasites and nutrition education. These are longterm measures applicable to situations where the prevalence and severity of anaemia are lower. Cost and time involved to meet the desired goals through these strategies are disproportionately high (53).

5. Iodine deficiency disorders (IDD)

Iodine deficiency is yet another major nutrition problem in India. Previously, iodine deficiency was equated with goitre. In recent years, it has become increasingly clear that iodine deficiency leads to a much wider spectrum of
disorders commencing with the intrauterine life and extending through childhood to adult life with serious health and social implications. Table 16 presents the iodine deficiency disorders in approximate order of increasing severity. The social impact of iodine deficiency arises not so much from goitre as from the effect on the central nervous system (56).

The problem

Whereas goitre has ceased to be a major problem in many developed countries (although not eradicated) it continues to be a serious health problem in many Third World Countries. For example iodine deficiency is a health problem of considerable magnitude in India and the neighbouring countries of Bangladesh, Bhutan, Myanmar, Indonesia, Nepal, Sri Lanka and Thailand. More people are affected and levels of severity are higher in South-East Asia than anywhere else in the world (99).

It has always been thought in India that goitre and cretinism were only found to a significant extent in the "Himalaya goitre belt" which is the world's biggest goitre belt. It stretches from Kashmir to the Naga Hills in the east, extending about 2,400 km and affecting the northern States of Jammu and Kashmir, Himachal Pradesh, Punjab, Haryana, Delhi, Uttar Pradesh, Bihar, West Bengal, Sikkim, Assam, Arunachal Pradesh, Nagaland, Mizoram, Meghalaya, Tripura and Manipur. In recent years renewed surveys outside the conventional goitre belt have identified endemic foci of iodine deficiency and the associated IDD in parts of Madhya Pradesh, Gujarat, Maharashtra, Andhra Pradesh, Kerala, Karnataka and Tamil Nadu. More and more new areas are being identified. Even areas near the sea coast like Bharuch district in Gujarat and Ernakulam district in Kerala are found goitre-affected. In short, no State in India can be said to be entirely free from goitre (Fig. 4).

![Goitre endemic areas in India](image)

The magnitude of the problem in India is far greater than what had been estimated in 1960s, when it was estimated that about 9 million persons were affected by goitre. Results of sample surveys conducted in 325 districts covering all the states/UTs have revealed that 263 districts are endemic where the prevalence of IDD is more than 10 per cent. It is estimated that more than 71 million persons are suffering from goitre and other iodine deficiency disorders in the country (100).

Goitre control

There are four essential components of national Iodine Deficiency Disorder control programme. These are iodized salt or oil, monitoring and surveillance, manpower training and mass communication.

1. Iodized salt

The iodization of salt is now the most widely used prophylactic public health measure against endemic goitre. In India the level of iodization is fixed under the Prevention of Food Adulteration (PFA) Act and is not less than 30 ppm at the production point, and not less than 15 ppm of iodine at the consumer level (98). Iodized salt is most economical, convenient and effective means of mass prophylaxis in endemic areas. Under the national IDD control activities, the Government of India proposed to completely replace common salt with iodized salt in a phased manner (98).

The National Institute of Nutrition at Hyderabad has come out with a new product, common salt fortified with iron and iodine. Community trials have been launched to examine the efficacy of the "two-in-one" salt (98).

iodised oil : Another method which has demonstrated its efficacy for controlling goitre is Intramuscular injection of iodized oil (mostly poppy-seed oil). Scientists at the National Institute of Nutrition, Hyderabad have now successfully developed a process to produce iodized oil in safflower or safoila oil (101).

The advantage of the injection procedure is that an average dose of 1 ml will provide protection for about 4 years. Although more expensive than iodated salt, this method has the advantage that it can be applied rapidly and in places where iodization of salt is not feasible or iodated salt is in short supply. However, the difficulty with this procedure is one of logistics, i.e., in reaching every victim or potential victim of IDD for the injection, which means that this approach is less practical.

iodized oil, oral : The oral administration of iodine as iodized oil or as sodium iodate tablets, is technically simpler than the injection method. Limited research has found that these procedures are effective against goitre but more costly than intramuscular injections.

2. Iodine monitoring

Countries implementing control programmes require a network of laboratories for iodine monitoring and surveillance. These laboratories are essential for a) iodine excretion determination b) determination of iodine in water, soil and food as part of epidemiological studies, and c) determination of iodine in salt for quality control.

Neonatal hypothyroidism is a sensitive pointer to environmental iodine deficiency and can thus be an effective indicator for monitoring the impact of a programme (99).

3. Manpower training

It is vital for the success of control that health workers and others engaged in the programme be fully trained in all aspects of goitre control including legal enforcement and public education.

4. Mass communication

Mass communication is a powerful tool for nutrition education. It should be fully used in goitre control work. Creation of public awareness is central issue of a successful public health programme.
5. Hazards of iodization

A mild increase in incidence of thyrotoxicosis has now been described following iodized salt programmes. An increase in lymphocytic thyroiditis (Hashimoto’s disease) has also been claimed. The risk of iodism or iodide goitre however seems to be very small (58).

6. Endemic fluorosis

In many parts of the world where drinking water contains excessive amounts of fluoride (3–5 mg/L), endemic fluorosis has been observed. Endemic fluorosis has been reported to be an important health problem in certain parts of the country, e.g., Andhra Pradesh (Nellore, Nalgonda and Prakasam districts), Punjab, Haryana, Karnataka, Kerala and Tamil Nadu (60). The toxic manifestation of fluorosis comprise the following:

(a) Dental fluorosis: Fluorosis of dental enamel occurs when excess fluoride is ingested during the years of tooth calcification – essentially during the first 7 years of life (101). It is characterized by “mottling” of dental enamel, which has been reported at levels above 1.5 mg/L intake (102). The teeth lose their shiny appearance and chalk-white patches develop on them. This is the early sign of dental fluorosis. Later the white patches become yellow and sometimes brown or black. In severe cases, loss of enamel gives the teeth a corroded appearance. Mottling is best seen on the incisors of the upper jaw. It is almost entirely confined to the permanent teeth and develops only during the period of formation (61).

(b) Skeletal fluorosis: This is associated with lifetime daily intake of 3.0 to 6.0 mg/L or more (102). There is heavy fluoride deposition in the skeleton. When a concentration of 10 mg/L is exceeded, crippling fluorosis can ensue (103). It leads to permanent disability.

(c) Genu valgum: A new form of fluorosis characterized by genu valgum and osteoporosis of the lower limbs has been reported in some districts of Andhra Pradesh and Tamil Nadu (104). The syndrome was observed among people whose staple was sorghum (jowar). Further studies showed that diets based on sorghum promoted a higher retention of ingested fluoride than do diets based on rice (14).

Intervention

(a) Changing the water source: One solution to the problem is to find a new source of drinking water with a lower fluoride content (0.5 to 0.8 mg/L) if that is possible. Running surface water contains lower quantities of fluorides than ground water sources such as wells. (b) Chemical treatment: If the above is not possible, the water can be chemically defluoridated in a water treatment plant, even though such treatment is moderately expensive (101). The National Environmental Engineering Research Institute, Nagpur developed a technique for removing fluoride by chemical treatment. It is called Nalgonda technique for defluoridation of water (105). It involves the addition of two chemicals (viz. lime and alum) in sequence followed by flocculation, sedimentation and filtration. (c) Other measures: Fluoride supplements should not be prescribed for children who drink fluoridated water. The use of fluoride toothpaste in areas of endemic fluorosis is not recommended for children up to 6 years of age (101).

7. Lathyrism

Lathyrism is a paralyzing disease of humans and animals. In the humans it is referred to as neurolathyrism because it affects the nervous system, and in animals as osteolathyrism (odoratism) because the pathological changes occur in the bones resulting in skeletal deformities (8). Neurolathyrism is a crippling disease of the nervous system characterized by gradually developing spastic paralysis of lower limbs, occurring mostly in adults consuming the pulse, Lathyrus sativus in large quantities.

The problem

Neurolathyrism is prevalent in parts of Madhya Pradesh, Uttar Pradesh, Bihar and Orissa. It has also been reported in Maharashtra, West Bengal, Rajasthan, Assam and Gujarat where the pulse is grown. The magnitude of the problem can be assessed from the fact that at one time in Rewa and Satna districts of Madhya Pradesh alone, there were 25,000 and 32,000 cases respectively. According to reports, there are no fresh outbreaks of the disease in endemic areas. This is attributed to the shifting trends in agronomical practices in the region (106). Lathyrism has also been reported to occur in Spain and Algeria where Lathyrus is eaten (8).

The pulse

Lathyrus sativus is commonly known as “Khesari dhal”. It is known by local names such as Teora dhal, Lak dhal, Baita, Gharas, Matra etc. (106). The seeds of lathyrus have a characteristic triangular shape and grey colour. When dehusked the pulse looks similar to red gram dhal or bengal gram dhal. Like other pulses, lathyrus is a good source of protein, but for its toxin which affects the nerves. It is eaten mostly by the poor agricultural labourer because it is relatively cheap. Studies have shown that diets containing over 30% of this dhal if taken over a period of 2–6 months will result in neurolathyrism.

The toxin

The toxin present in lathyrus seeds has been identified as Beta oxalyl amino alanine (BOAA). It has been isolated in crystalline form and is water soluble; this property has been made use of in removing the toxin from the pulse by soaking it in hot water and rejecting the soak water. Studies indicate that there is a blood-brain barrier to this toxin. In order to overcome this barrier, the pulse must be eaten in large amounts over a period of time for 2 months or more. Besides BOAA several other toxins have also been reported (107).

The disease

The disease affects mainly young men between the age of 15 to 45 years and manifests itself in stages: (a) Latent stage: The individual is apparently healthy, but when subjected to physical stress exhibits ungrainy gait. Neurological examination shows characteristic physical signs. This stage is considered important from the preventive aspect, since at this stage, if the pulse is withdrawn from the diet, it will result in complete remission of the disease. (b) No-stick stage: The patient walks with short jerky steps without the aid of a stick. A large number of patients are found in this stage. (c) One-stick stage: The patient walks with a crossed gait with a tendency to walk on toes. Muscular stiffness makes it necessary to use a stick to maintain balance. (d) Two-stick stage: The symptoms are more severe. Due to excessive bending of knees and crossed legs, the patient needs two crutches for support. The gait is slow and clumsy and the patient gets tired easily after walking a short distance. (e) Crawler stage: Finally the erect posture becomes impossible as the knee joints cannot support the weight of the body. There is atrophy of the thigh muscles.
and leg muscles. The patient is reduced to crawling by throwing his weight on his hands (106).

Interventions

The possible interventions for the prevention and/or control of lathyrism are:

(a) Vitamin C prophylaxis: Although this condition is believed to be irreversible, in certain instances the damage could be repaired by the daily administration of 500–1000 mg of ascorbic acid for a week or so. The damage could also be prevented by generous provision of ascorbic acid in the lathyrogenic diet, as demonstrated in guinea pigs and monkeys.

(b) Banning the crop: This is an extreme step not feasible for immediate implementation. The Prevention of Food Adulteration Act in India has banned lathyrus in all forms—whole, split or flour. But the ban is not operative where it is needed, viz. Madhya Pradesh, Bihar, Orissa and Gujarat where the pulse is widely grown.

If however, it is not possible to avoid consuming khesari dal, it is desirable that the proportion of the dal should never form more than a quarter of the total amount of cereals and pulses eaten per day

(c) Removal of toxin

(1) Steeping method: Since the toxins are water soluble, they can be removed by soaking the pulse in hot water. This method can be practised at home. A large quantity of water is boiled and the pulse is soaked in hot water for 2 hours, after which the soaked water is drained off completely. The pulse is washed again with clean water, then drained off and dried in the sun. The pulse is then used for consumption. The drawback with this method is that it entails loss of vitamins and minerals

(2) Parboiling: An improved method of detoxicating the pulse is "parboiling" as is done in the case of parboiled rice. This technique is suitable for large scale operation. Simple soaking in lime water overnight followed by boiling is credited to destroy the toxin. This treatment also destroys trypsin inhibitors. Lime is easily available as it is used with betel leaves.

(c) Education: The public must be educated on the dangers of consuming this pulse and the need for removing its toxin before consumption.

(d) Genetic approach: Certain strains of lathyrus contain very low levels of toxin (0.1%). The selective propagation and cultivation of such strains may be the most effective way to eradicate lathyrism without any drastic change in the food habits of the people. Low toxin varieties can be obtained from the Indian Agricultural Research Institute, New Delhi.

(e) Socio-economic changes: In the final analysis, it is only socio-economic changes or overall development that can root out lathyrism.

NUTRITIONAL FACTORS IN SELECTED DISEASES

1. Cardiovascular disease

It is now generally agreed that diet governs many situations favouring the onset of "heart disease", particularly coronary heart disease. Of all the factors associated with CHD (e.g., plasma cholesterol, high blood pressure, cigarette smoking, lack of physical activity) plasma cholesterol has a very high statistical significance with the incidence of CHD. The risk of CHD appears to increase as the plasma cholesterol concentration rises (108). Various studies have supported the role of elevated blood levels of cholesterol and low density lipoproteins (LDL) in the development of atherosclerosis. Geographical studies have shown that there is no population in whom CHD is common that does not have a relatively high mean level of plasma total cholesterol (TC) in adults (15). These observations have been reinforced by metabolic studies. In addition trials of the effect of dietary changes on CHD have suggested that altering the fatty acid composition of the diet in favour of greater intake of polyunsaturated fatty acids (PUFA) and less intake of saturated fats, while restricting the intake of fat calories to less than 30 per cent of the total calories, may lower the risk that CHD will subsequently develop (109).

The evidence of association is now so strong for cholesterol and CHD that the WHO Expert committee (1982) considered its effect to be "causal" in populations although this cannot be claimed yet for individuals (15). The WHO Expert Committee (15) concludes that there is a well established triangular relationship between habitual diet, blood cholesterol levels and CHD. The current report of the expert group of the ICMR (2010) on Nutrient Requirement and Recommended Dietary Allowances for Indians endorses the views.

Cholesterol

Cholesterol occurs in all foods of animal origin. Part of it is synthesized in the body. The plasma cholesterol is determined by (a) the amount absorbed from food (b) the amount synthesized in the body (c) the rate of catabolism and excretion in the bile (d) intestinal reabsorption of bile acids, and (e) the equilibrium between plasma and tissues. The extent to which cholesterol intake influences total cholesterol levels is highly variable.

Lipoproteins

Cholesterol is carried in plasma lipoproteins. Lipoproteins are divided into four major classes—chylomicrons, very low-density lipoproteins (VLDLs), low-density lipoproteins (LDLs) and high-density lipoproteins (HDLs). The total serum cholesterol is the sum of the cholesterol in 3 lipoprotein fractions, viz. VLDL, LDL, and HDL cholesterol. Most of the serum cholesterol (close to 50 per cent) is in LDL. Whereas LDL is dominated by its cholesterol content, VLDL is dominated by its triglyceride content.

LDL has been shown to function in the delivery of cholesterol to body cells. Excessive level of LDL thus leads to the accumulation of cholesterol in tissue cells particularly the smooth muscle cells of the vascular system. It is thus involved in the arteriosclerotic process. In contrast, HDL functions in the removal of cholesterol from cells. This mechanism underlines its protective effect in CHD. From long-term observations it became quite clear that HDL levels, the higher they are, the more protective they seem to be against CHD.

Fatty acids

In populations where the plasma cholesterol is high, there is also generally a high consumption of saturated fats. Clinical studies on selected volunteers under well-defined conditions have clearly demonstrated that a high intake of saturated fatty acids over several weeks or months causes an increase in plasma cholesterol. The cholesterol-raising effect is mainly produced by C12, C14 and C16 acids; stearic acid
and fatty acids with less than 12 carbon atoms have a smaller effect on plasma cholesterol. The mechanisms by which these saturated fatty acids act (possibly on cholesterol synthesis) is not fully known.

Dietary unsaturated fatty acids with two or more double bonds have been shown to lower plasma cholesterol. The mechanism of reduction of serum cholesterol by polyunsaturated fatty acids is not clear but includes reduced synthesis of VLDL. The proposition has often been made that a low HDL/LDL ratio favours the development of atheroma, thus favouring the onset of CHD (110).

Polyunsaturated fatty acids (e.g., linoleic and arachidonic acids) have an additional role, that is, to inhibit platelet aggregation and thus prevent thrombus formation. Recent research indicates that arachidonic acid metabolizes in the vascular endothelium to form two important metabolites, namely prostacyclin and thromboxane (Fig. 5). These two compounds have opposing effects on the cardiovascular system. Whereas thromboxane induces platelet aggregation, prostacyclin inhibits the same and prevents intravascular thrombus formation. Prostacyclin was found also to relax coronary blood vessels, thus opposing the action of thromboxane. It has been suggested that generation of prostacyclin is the biochemical mechanism underlying the well-known ability of blood vessels to resist platelet aggregation. Linoleic acid which is the main precursor of arachidonic acid is therefore regarded as the body's best bulwark against CHD. In short, essential fatty acids have in the last decade come to be regarded as of major importance in clinical nutrition.

In a very large proportion of individuals with a raised cholesterol level, the blood concentration of triglycerides (TG) is also markedly increased. Some workers have indeed claimed that correlation between TG and CHD is as good as that between total serum cholesterol and CHD. It has been shown that TG levels act as a significant independent risk factor for CHD (102). Both cholesterol and TG are associated with specific proteins in the plasma to form lipoproteins.

The most important determinant of TG level is the activity of the enzyme, lipoprotein lipase in the endothelial lining of the capillaries and in a variety of tissues. This enzyme removes TG particularly from the very low density lipoproteins (VLDL) and converts these to the lipoproteins of higher density. In certain genetically determined diseases, this enzyme may be absent. A reduction in its activity or a reduced capacity to deal with increased levels of TG may be important in more common diseases such as diabetes where high concentrations of TG are often observed.

**Carbohydrate**

Coronary heart disease rates are lowest in populations eating high carbohydrate diets. Support for the hypothesis that consumption of complex carbohydrates may decrease the risk of CHD comes from historical trends of food consumption patterns and mortality rates in US. It is generally recognized that such mortality rates were quite low until about 1920. After 1920 there was a steady increase in the mortality rate until 1968 when a decline began (109). The principal nutritional change that has occurred since the early 1920 has been a decrease in the consumption of dietary carbohydrate. Further support comes from feeding studies. A decrease in serum cholesterol was observed during the vegetable feeding period. Neither high carbohydrates nor high sucrose feeding has induced atherosclerosis in animals. An inverse association of fibre intake with the risk of CHD has also been observed (111).

**Salt**

There are good and consistent correlations between dietary sodium intake and the incidence of hypertension. Thus the highest incidence of hypertension is found in north Japan where the sodium intake is above 400 mmol/day, while primitive societies ingesting less than 60 mmol/day have virtually no hypertension. Susceptible individuals in primitive populations who change from low to high intake of sodium have been found to develop hypertension. Hypertension can be successfully treated with a drastically low sodium diet (less than 10 mmol/day (110).

**2. Diabetes**

In a diabetic, there is impaired metabolism of glucose in the body, which leads to excess of glucose in blood and urine. Insulin helps in checking and maintaining the level of glucose in blood. Insulin deficiency leads to accelerated utilization of energy reserves from fat stores. The fatty acids are oxidized by liver to ketone bodies. Excess of ketone bodies leads to their accumulation in urine. This condition is known as ketoacidosis and can result in diabetic coma. Due to insulin deficiency excess of fatty acids are converted to triglycerides. In diabetes these accumulate in the blood. Insulin is also important for synthesis of proteins and deficiency of insulin leads to muscle wasting.
A reduction in dietary fat may alter the risk of breast cancer prolactin release (119).

However, no known carcinogen has yet been identified from bacterial flora into carcinogen or co-carcinogens (117). Of bile acids in the bowel which are then metabolized by cancer (116). Dietary fat is believed to increase the secretion is stepped up, thus leading to a state of cell membrane. Through a feedback mechanism the insulin secretion is normal or increased. The large adipocyte can be attributed to the decreased affinity of the insulin receptors or to a reduction in their number in the cell membrane. Through a feedback mechanism the insulin secretion is stepped up, thus leading to a state of hyperinsulinism.

It is known that a relative insulin resistance takes place in obesity in peripheral tissues, mainly adipose tissues, while the insulin secretion is normal or increased. The demonstrated reduction in the sensitivity to insulin of the large adipocyte can be attributed to the decreased affinity of the insulin receptors or to a reduction in their number in the cell membrane. Through a feedback mechanism the insulin secretion is stepped up, thus leading to a state of hyperinsulinism.

It is postulated that 80 per cent of cancers may be due to environmental factors, and it is possible that some dietetic factors may be involved. Existing knowledge is reviewed briefly as below:

(a) Dietary fat

Population surveys have shown a strong positive correlation between cancer colon and dietary intake of fat (115). It has been suggested that the high fat intake accounts for the high incidence of colon cancer in Western communities. In Japan, recent increases in fat consumption have been associated with striking increase in rates of colon cancer (116). Dietary fat is believed to increase the secretion of bile acids in the bowel which are then metabolized by bacterial flora into carcinoen or co-carcinogens (117). However, no known carcinoen has yet been identified from faeces and the evidence is thus incomplete.

Positive correlation between per capita consumption of dietary fat and breast cancer rates has also been noted. A reduction in dietary fat may alter the risk of breast cancer (118), perhaps by increasing oestrogen production or prolactin release (119).

(b) Dietary fibre

Several studies indicate that the risk of colon cancer is inversely related to the consumption of dietary fibre, which may protect against intestinal carcinogens or precursors by dilutional or other effects (120). Although the available epidemiological data are not entirely consistent, the weight of evidence generally supports the hypothesis that fibre protects against colon cancer (116).

(c) Micronutrients

Micronutrients may also have a protective influence, since cancers of the lung and several other sites have been associated with a low intake of vitamin A (117). The risk of stomach cancer has been related to a deficiency of vitamin C, which may act by inhibiting the formation of carcinogenic nitrosamines in the stomach (121). Trace elements (e.g., selenium) have also been implicated in the aetiology of cancer (116).

(d) Food additives and contaminants

Several studies indicate that the risk of colon cancer is inversely related to the consumption of dietary fibre, which may protect against intestinal carcinogens or precursors by dilutional or other effects (120). Although the available epidemiological data are not entirely consistent, the weight of evidence generally supports the hypothesis that fibre protects against colon cancer (116).

(e) Alcohol

Heavy drinking increases the risk of liver cancer. It is estimated that alcohol contributes to about 3 per cent of all cancer deaths (124). Some recent studies have suggested that beer consumption may be related to cancer rectum, but the association has not been confirmed (117).

The above review indicates that much evidence has accumulated to indicate that nutrition has an influence on cancer incidence and mortality. There is in this field a remarkable dearth of facts and an abundance of speculation.

ASSESSMENT OF NUTRITIONAL STATUS

The nutritional status of an individual is often the result of many interrelated factors. It is influenced by the adequacy of food intake both in terms of quantity and quality and also by the physical health of the individual (125). The nutritional status of a community is the sum of the nutritional status of the individuals who form that community. The main objective of a "comprehensive" nutritional survey is to obtain precise information on the prevalence and geographic distribution of nutritional problems of a given community, and identification of individuals or population groups "at risk" or in greatest need of assistance. In the absence of this information, problems cannot be defined and policies formulated. The purpose of nutritional
assessment is to develop a health care programme that meets the needs defined by that assessment, including evaluation of the effectiveness of such programmes (58).

In nutritional surveys, it is not necessary to examine all the persons in a given community. Examination of a random and representative sample of the population covering all ages and both sexes in different socio-economic groups is sufficient to be able to draw valid conclusions. All surveys should be planned with the aid of expert statistical advice. Decisions of many kinds have to be made in advance: duration of survey; type of survey whether cross-sectional or longitudinal; standardization of measurement techniques and survey instruments, etc. Opportunity might be taken of conducting, perhaps on a sub-sample, an intensive investigation of nutritional status.

Assessment methods

The assessment of the nutritional status involves various techniques. Proper evaluation demands a many-angled approach, covering all the different stages in the natural history of nutritional diseases, including prepathogenesis stage as shown in Fig. 6 (126).

The assessment methods include the following:

1. Clinical examination;
2. Anthropometry;
3. Biochemical evaluation;
4. Functional assessment;
5. Assessment of dietary intake;
6. Vital and health statistics; and
7. Ecological studies.

The different methods used for the appraisal of nutritional status are not mutually exclusive; on the contrary, they are complimentary.

1. Clinical examination

Clinical examination is an essential feature of all nutritional surveys since their ultimate objective is to assess levels of health of individuals or of population groups in relation to the food they consume. It is also the simplest and the most practical method of ascertaining the nutritional status of a group of individuals. There are a number of physical signs, some specific and many non-specific, known to be associated with states of malnutrition. When two or more clinical signs characteristic of a deficiency disease are present simultaneously, their diagnostic significance is greatly enhanced. A WHO Expert Committee (127) classified signs used in nutritional surveys into three categories as those:

(a) not related to nutrition, e.g., alopecia, pyorrhoea, pterygium;
(b) that need further investigation, e.g., malar pigmentation, corneal vascularization, geographic tongue; and
(c) known to be of value, e.g., angular stomatitis, Bitot’s spots, calf tenderness, absence of knee or ankle jerks (beri-beri), enlargement of the thyroid gland (endemic goitre), etc.

However, clinical signs have the following drawbacks:
(a) malnutrition cannot be quantified on the basis of clinical signs (b) many deficiencies are unaccompanied by physical signs and (c) lack of specificity and subjective nature of most of the physical signs. To minimize subjective and objective errors in clinical examination, standard survey forms or schedules have been devised covering all areas of the body. A specimen nutrition assessment schedule is given at the end of this chapter (Annexure I).

2. Anthropometry

Anthropometric measurements such as height, weight, skinfold thickness and arm circumference are valuable indicators of nutritional status. In young children, additional measurements such as head and chest circumference are made. If anthropometric measurements are recorded over a period of time, they reflect the patterns of growth and development, and how individuals deviate from the average at various ages in body size, build and nutritional status. Anthropometric data can be collected by non-medical personnel, given sufficient training. This subject is discussed in detail in Chapter 10.

3. Laboratory and biochemical assessment

(a) LABORATORY TESTS:

(i) Haemoglobin estimation: It is the most important laboratory test that is carried out in nutrition surveys. Haemoglobin level is a useful index of the

overall state of nutrition irrespective of its significance in anaemia. An RBC count and a haematocrit determination are also valuable. (ii) Stools and urine: Stools should be examined for intestinal parasites. History of parasitic infestation, chronic dysentery and diarrhoea provides useful background information about the nutritional status of persons. Urine should also be examined for albumin and sugar.

(b) BIOCHEMICAL TESTS: With increasing knowledge of the metabolic functions of vitamins and minerals, assessment of nutritional status by clinical signs has given way to more precise biochemical tests which may be applied to measure individual nutrient concentration in body fluids (e.g., serum retinol, serum iron) or detection of abnormal amounts of metabolites in urine (e.g., urinary iodine) frequently after a loading dose, or measurement of enzymes in which the vitamin is a known co-factor (for example in riboflavin deficiency) to help establish malnutrition in its preclinical stages.

Biochemical tests are time-consuming and expensive. They cannot be applied on a large scale, as for example in the nutritional assessment of a whole community. They are often carried out on a subsample of the population. Most biochemical tests reveal only current nutritional status; they are useful to quantify mild deficiencies. If the clinical examination has raised a question, then the biochemical tests may be invoked to prove or disprove the question raised. A short list of currently advocated biochemical tests applicable in nutritional surveys is given in Table 31.

5. Assessment of dietary intake

The value of nutritional assessment is greatly enhanced when it is supplemented by an assessment of food consumption. Direct assessment of food consumption involves dietary surveys which may be household inquiries or individual food consumption surveys. Well organized survey methods for this purpose are available (130, 131).

A diet survey may be carried out by one of the following methods: (i) WEIGHMENT OF RAW FOODS: This is the method widely employed in India as it is practicable and if properly carried out is considered fairly accurate. The survey team visits the households, and weighs all food that is going to be cooked and eaten as well as that which is wasted or discarded. The duration of the survey may vary from 1 to 21 days, but commonly 7 days which is called "one dietary cycle". (ii) WEIGHMENT OF COOKED FOODS: Foods should preferably be analyzed in the state in which they are normally consumed, but this method is not easily acceptable among people. (iii) ORAL QUESTIONNAIRE METHOD: This is useful in carrying out a diet survey of a large number of people in a short time. Inquiries are made retrospectively about the nature and quantity of foods eaten during the previous 24 or 48 hours. If properly carried out, oral questionnaire method can give reliable results. A diet survey may also include collection of data relating to dietary habits and practices.

The data that is collected have to be translated into (a) mean intake (grams) of food in terms of cereals, pulses, vegetables, fruits, milk, meat, fish and eggs, and (b) the mean intake of nutrients per adult man value or "consumption unit". This exercise requires the use of suitable tables of food composition. An excellent guide for carrying out this analysis is the Indian Council of Medical Research (ICMR) publication: "Nutritive Value of Indian Foods" (43).

A diet survey provides information about dietary intake patterns, specific foods consumed and estimated nutrient intakes. It indicates relative dietary inadequacies as judged by present standards. Not only will such information be valuable for planning health education activities, but it will also allow an assessment to be made of the extent and...
nature of changes needed in the agriculture and food production industries.

6. Vital statistics

An analysis of vital statistics - mortality and morbidity data - will identify groups at high risk and indicate the extent of risk to the community. Mortality in the age group 1 to 4 years is particularly related to malnutrition. In developing countries, it may be as much as 20 times that in countries such as Australia, Denmark or France. The other rates commonly used for this purpose are: infant mortality rate, second-year mortality rate, rate of low birth-weight babies and life expectancy. These rates are influenced by nutritional status and may thus be indices of nutritional status. Mortality data, however, do not provide a satisfactory picture of the nutritional status of a population (132).

Data on morbidity (e.g., hospital data or data from community health and morbidity surveys) particularly in relation to protein energy malnutrition, anaemia, xerophthalmia and other vitamin deficiencies, endemic goitre, diarrhoea, measles and parasitic infestations can be of value in providing additional information contributing to the nutritional status of the community.

7. Assessment of ecological factors

Malnutrition is the end result of many interacting ecological factors. In any nutrition survey it is necessary to collect ecological information of the given community in order to make the nutrition assessment complete. A study of the ecological factors comprise the following: (a) FOOD BALANCE SHEET: This is an indirect method of assessing food consumption, in which supplies are related to census population to derive levels of food consumption in terms of per capita supply availability. The estimate refers to the country as a whole, and so conceals differences which may exist between regions, and among economic, age and sex groups. The great advantage of this method is that it is cheaper and probably simpler than any method of direct assessment. Used intelligently, this method does give an indication of the general pattern of food consumption in the country. (b) SOCIO-ECONOMIC FACTORS: Food consumption patterns are likely to vary among various socio-economic groups. Family size, occupation, income, education, customs, cultural patterns in relation to feeding practices of children and mothers, all influence food consumption patterns. (c) HEALTH AND EDUCATIONAL SERVICES: Primary health care services, feeding and immunization programmes should also be taken into consideration. (d) CONDITIONING INFLUENCES: These include parasitic, bacterial and viral infections which precipitate malnutrition. It is necessary to make an "ecological diagnosis" of the various factors influencing nutrition in the community before it is possible to put into effect measures for the prevention and control of malnutrition.

**NUTRITIONAL SURVEILLANCE**

The concept of nutritional surveillance is derived from disease surveillance. Nutritional surveillance has been defined as "keeping watch over nutrition, in order to make decisions that will lead to improvement in nutrition in population" (133). Three distinct objectives have been defined for surveillance systems: (a) to aid long-term planning in health and development, (b) to provide input for programme management and evaluation, and (c) to give timely warning and intervention to prevent short-term food consumption crises (133, 134).

---

**Nutritional surveillance and growth monitoring**

Nutritional surveillance should not be confused with growth monitoring. The differences are shown in Table 33.

Growth monitoring is oriented to the individual child, and is a dynamic measure of its health from month to month. It focuses on normal nutrition and the means to promote continued growth and good health. It requires enrolment of the infant at an early stage, preferably before 6 months. Regular monthly participation is crucial to detect early onset of growth faltering.

Nutritional surveillance, on the other hand, can be carried out on a representative sample of children in the community. It gives a reliable idea of the overall nutritional condition of village (or area) A - whether it is good or bad, is better or worse than that of village B or C (and so requires supplies and personnel), and whether it is improving or deteriorating with time. It can help to diagnose malnutrition and assess the impact of occurrence like drought or measures designed to alleviate malnutrition in the community at large.

Nutritional status indicators

Indicators that are considered useful for the surveillance of nutritional status are given in Table 34. There is an increasing trend to use nutritional indicators to measure quality of life, specially as a means of evaluating both development programmes and health programmes. Many of the indicators used in nutritional surveillance are the same as the socio-economic and health status indicators recommended for monitoring progress in health.

SOCIAL ASPECTS OF NUTRITION

Food means not only proteins, fats, minerals, vitamins and other nutrients — but much more; it is part of security and civilization. Nations and civilizations are linked together not only by ideas, but also by bread. Hunger and malnutrition are problems everywhere and have harassed mankind and threatened peace throughout history. It is no wonder that the growing incidence of hunger and malnutrition should have come to the forefront of international concern.

Problem of malnutrition

Malnutrition has been defined as “a pathological state resulting from a relative or absolute deficiency or excess of one or more essential nutrients”. It comprises four forms — undernutrition, overnutrition, imbalance and the specific deficiency (136). (1) Undernutrition: This is the condition which results when insufficient food is eaten over an extended period of time. In extreme cases, it is called starvation. (2) Overnutrition: This is the pathological state resulting from the consumption of excessive quantity of food over an extended period of time. The high incidence of obesity, atheroma and diabetes in western societies is attributed to overnutrition. (3) Imbalance: It is the pathological state resulting from a disproportion among essential nutrients with or without the absolute deficiency of any nutrient. (4) Specific deficiency: It is the pathological state resulting from a relative or absolute lack of an individual nutrient.

On a global scale the five principal nutritional deficiency diseases that are being accorded the highest priority action are wasting, stunting, xerophthalmia, nutritional anaemias and endemic goitre. These diseases represent the tip of the “iceberg” of malnutrition; a much larger population are affected by “hidden” malnutrition which is not easy to diagnose.

The effects of malnutrition on the community are both direct and indirect. The direct effects are the occurrence of frank and subclinical nutrition deficiency diseases such as kwashiorkor, marasmus, vitamin and mineral deficiency diseases. The indirect effects are a high morbidity and mortality among young children (nearly 50 per cent of total deaths in the developing countries occur among children under-5 years of age as compared to less than 5 per cent in developed countries), retarded physical and mental growth and development (which may be permanent), lowered vitality of the people leading to lowered productivity and reduced life expectancy. Malnutrition predisposes to infection and infection to malnutrition; and the morbidity arising therefrom as a result of complications from such infectious diseases as tuberculosis and gastro-enteritis is not inconsiderable. The high rate of maternal mortality, stillbirth and low birth-weight are all associated with malnutrition.

In the more developed countries of the world nutritional problems are somewhat different. Overnutrition is encountered much more frequently than undernutrition. The health hazards from overnutrition are a high incidence of obesity, diabetes, hypertension, cardiovascular and renal diseases, disorders of liver and gall bladder. From this brief review, it is obvious that the consequences of malnutrition are ominous.

Ecology of malnutrition

Malnutrition is a man-made disease. It is a disease of human societies. It begins quite commonly in the womb and ends in the grave. The great advantage of looking at malnutrition as a problem in human ecology is that it allows for variety of approaches towards prevention. Jelliffe (1966) (136) listed the ecological factors related to malnutrition as follows: conditioning influences, cultural influences, socio-economic factors, food production and health and other services.

(1) Conditioning influences: Infectious diseases are an important conditioning factor responsible for malnutrition, particularly in small children. Diarrhoea, intestinal parasites, measles, whooping cough, malaria, tuberculosis all contribute to malnutrition. In fact it is a vicious circle — infection contributing to malnutrition, and malnutrition causing an otherwise minor childhood ailments to become killers. It has been shown that where environmental conditions are poor, small children may suffer from some infection or the other for almost half of their first three years of life. The interrelationship between malnutrition and infection has been well documented.

(2) Cultural influences: Lack of food is not the only cause of malnutrition. Too often there is starvation in the midst of plenty. People choose poor diets when good ones are available because of cultural influences which vary widely from country to country, and from region to region. These may be stated as follows: (a) Food habits, customs, beliefs, traditions and attitudes: Food habits are among the oldest and most deeply entrenched aspects of any culture. They have deep psychological roots and are associated with love, affection, warmth, self image and social prestige. The family plays an important role in shaping the food habits, and these habits are passed from one generation to another.
Rice is the staple cereal in the eastern and southern States of India and wheat is the staple cereal in the northern States. During the second World War, when wheat was made available in place of rice in South India people refused to buy wheat because it was not their staple cereal. The story is told of a Philippine student who died of beriberi after writing an essay explaining how the disease could be prevented. The crux of the problem is that many customs and beliefs apply most often to vulnerable groups, i.e. infants, toddlers, expectant and lactating women. Papaya is avoided during pregnancy because it is believed to cause abortion. In Gujarat, valuable foods such as dhals, leaf greens, rice and fruits are avoided by the nursing mother. There is a widespread belief that if a pregnant woman eats more, her baby will be big and delivery difficult. Certain foods are "forbidden" as being harmful for the child. Then there are certain beliefs about hot and cold foods, light and heavy foods. (b) Religion: Religion has a powerful influence on the food habits of the people. Hindus do not eat beef, and Muslims pork. Some orthodox Hindus do not eat meat, fish, eggs and certain vegetables like onion. These are known as food taboos which prevent people from consuming nutritious foods even when these are easily available. (c) Food fads: In the selection of foods, personal likes and dislikes play an important part. These are called "food-fads". The food fads may stand in the way of correcting nutritional deficiencies. (d) Cooking practices: Draining away the rice water at the end of cooking, prolonged boiling in open pans, peeling of vegetables, all influence the nutritive value of foods. (e) Child rearing practices: These vary widely from region to region and influence the nutritional status of infants and children. Examples of this situation are premature curtailment of breast feeding, the adoption of bottle feeding and adoption of commercially produced refined foods. (f) Miscellaneous: In some communities, men eat first and women eat last and poorly. Consequently, the health of women in these societies may be adversely affected. Chronic alcoholism is another factor which may lead to serious malnutrition.

(3) SOCIO-ECONOMIC FACTORS: Malnutrition is largely the by-product of poverty, ignorance, insufficient education, lack of knowledge regarding the nutritive value of foods, inadequate sanitary environment, large family size, etc. These factors bear most directly on the quality of life and are the true determinants of malnutrition in society. The speed with which populations are growing in many developing countries is another important factor to reckon with. It has made the solution of the malnutrition problem more difficult. In short, the causes of malnutrition are built into the very nature of society, in the socio-economic and political structures, both nationally and internationally (137).

(4) FOOD PRODUCTION: Increased food production should lead to increased food consumption. The average Indian has 0.6 hectare of land surface compared to 5.8 hectare per head in the developed countries. The per capita arable land for an average Indian is only 0.3 hectare (136). Yields per hectare are only about one-fourth of those achieved in the industrialized countries. Given the best technology known at present, most developing countries could increase their food production several fold. But increased food production will not solve the basic problem of hunger and malnutrition in much of the developing world. Scarcity of food, as a factor responsible for malnutrition, may be true at the family level; but it is not true on a global basis, nor is it true for most of the countries where malnutrition is still a serious problem. It is a problem of uneven distribution between the countries and within the countries. It is said that there will be very little malnutrition in India today if all the food available can be equitably distributed in accordance with physiological needs (139).

(5) HEALTH AND OTHER SERVICES: The health sector can, if properly organized and given adequate resources can combat malnutrition. Some of the remedial actions that can be taken up by the health sector are: (1) Nutritional surveillance: Nutritional surveillance implies the continuous monitoring in a community or area of factors or conditions which indicate, relate to, or impinge on the nutritional status of individuals or groups of people (WHO, 1976) (140). The first task is to identify the groups and individuals affected — through clinical examination and simple body measurements of persons attending health centres and hospitals. A further step is to carry out surveys in the villages. The data will give a more realistic picture of the nutritional status of the community. (2) Nutritional rehabilitation: Immediate measures are required as soon as the malnourished subjects are located. Children suffering from severe PEM with complications need urgent care, may be in a hospital. Less severely affected children can be treated on a domiciliary basis or in special nutrition rehabilitation centres. These centres should be linked with health centres. (3) Nutrition supplementation: The target groups are mothers and children. Supplementary feeding is normally regarded as a stop-gap measure for the rehabilitation of malnourished children. (4) Health education: It is opined that by appropriate educational action, about 50 per cent of nutritional problems can be solved. Health education programmes in nutrition is often a weak component. Its reinforcement is a key element in all health services development.

Preventive and social measures

Since malnutrition is the outcome of several factors, the problem can be solved only by taking action simultaneously at various levels — family, community, national and international levels. It requires a coordinated approach of many disciplines — nutrition, food technology, health administration, health education, marketing, etc. In short, it calls for a comprehensive programme of social development of the entire country.

ACTION AT THE FAMILY LEVEL

The principal target of nutritional improvement in the community is the family, and the instrument for combating malnutrition at the family level is nutrition education. The housewife is the "manager" to the consumption of foods in the family. In some families, the husband determines what foods will reach the table. Both the husband and the wife need to be educated on the selection of right kinds of local foods and in the planning of nutritionally adequate diets within the limits of their purchasing power. Harmful food taboos and dietary prejudices can be identified and corrected. Since food expenditure often amounts to 50–70 per cent of family budgets, nutrition education programmes should be a good investment (141). The promotion of breast-feeding and improvement in infant and child feeding practices are the two areas where nutrition education can have a considerable effect. Action is also needed to counter misleading commercial advertising with regard to baby foods. Attention should also be focused on the nutritional needs of expectant and nursing mothers and children in the family. The shortage of protective foods can be met to some extent by planning a kitchen garden or keeping poultry. Adequate nutrition can be obtained in most countries with a combination of locally available and acceptable foods. Other related activities at the family level
are the “package” of mother and child health, family planning and immunization services. The community health workers and the multipurpose workers are the kind of people in key positions to impart nutrition education to the families in their respective areas.

**ACTION AT THE COMMUNITY LEVEL**

Action at the community level should commence with the analysis of the nutrition problem in terms of (a) the extent, distribution and types of nutritional deficiencies; (b) the population groups at risk; and (c) the dietary and non-diary factors contributing to malnutrition. To obtain this information, diet and nutrition surveys in carefully chosen representative population samples will have to be carried out using standardized methodologies which will permit comparisons in time and space. Having obtained information about the magnitude of the nutrition problem in the community, the next important step will be to plan realistic and feasible approaches to the control of the problem based on local resources. In many developing countries such as India, it is usual to start with direct intervention measures such as supplementary feeding programmes, midday school meals, vitamin A prophylaxis programme, but these will only provide palliative, partial or temporary solutions. The real permanent solution can only come from fundamental measures that will correct the basic causes of malnutrition. This implies, first of all, increasing the availability of foods both in quantity and quality, but—much more important—making sure that the people suffering or at risk of malnutrition can obtain these foods. The Applied Nutrition Programme is an attempt at production of various types of protective foods by the community for the community. The Integrated Child Development Services (ICDS) Programme makes a concerted and coordinated effort to deliver a basic minimum package consisting of supplementary nutrition, immunization, health check-ups, health and nutrition education for the mothers and non-formal education for the preschool age children. The target groups are children up to six years, pregnant and lactating women, and other women in the age group 15 to 44 years. Significant improvements in the overall living conditions of the people is also called for at the community level. This includes such measures as health education, improvement of water supply, control of infectious diseases. In brief, a broad socio-economic development of the entire community is called for.

**ACTION AT THE NATIONAL LEVEL**

The burden of improving the nutritional status of the people, by and large, is the responsibility of the State. The ninth Report of the Joint FAO/WHO Expert Committee on Nutrition (1976) (140) suggested several new approaches and strategies for action at the national level. Some of the strategies and approaches undertaken at the national level in India are: (1) Rural development: The nutritional uplift of people, especially in a country like India, can come about only as part and parcel of an overall socio-economic development of rural areas where 72 per cent of people live. Even an impressive increase in total food production will not solve the problem of undernutrition if the income levels of vast sections of the people continue to be so low that they cannot afford to buy the foods they need. It is therefore necessary to raise the living standards and purchasing power of the people. This implies a broad-based programme of rural development. (2) Increasing agricultural production: The food production potential is still greatly under-utilized. It must keep pace with population growth. This implies application of modern farming practices, the expansion of cultivated areas, the use of fertilizers, better seeds, and so on. Increased food production is meaningless if not accompanied by an effective food distribution system. This implies marketing, land tenure and food price policies. Irrigation projects undertaken to increase food production could be counter-productive if parallel measures aimed at prevention of mosquito-breeding and other vector control measures are not built into the programmes. (3) Stabilisation of population: The population policy in India is related to food and nutrition policy. The accent now is on birth spacing and a small family norm. (4) Nutrition intervention programmes: Several nutritional problems of developing countries today can be mitigated, if not entirely solved by short-term programmes. The prevention and control of endemic goitre through iodized common salt; the control of anaemia through distribution of iron and folic acid tablets to pregnant and nursing mothers, or possibly through fortification of common foods with iron; the control of nutritional blindness through periodic administration of massive oral doses of vitamin A to children at risk; supplementary feeding programmes for preschool children are examples of such measures. These programmes have a direct impact on the health and nutritional status of particular segments of the population. These programmes alleviate the situation as a temporary measure. (5) Nutrition related health activities: Several programmes within the field of health, seemingly unrelated to nutrition, may have a profound impact on the nutritional status. The National Malaria Eradication Programme, by opening up vast tracts of land for cultivation, has made an outstanding contribution to health and nutrition. Since malnutrition is closely related to infection, all programmes of immunization and improvement of environmental sanitation will inevitably have a beneficial effect on nutrition. Programmes of family planning could make a major contribution to the improvement of nutritional status of mothers and children. All these programmes may be considered as alternative approaches to improving the nutritional status of the people. The FAO/WHO Expert Committee on Nutrition (1976) stressed that food and nutrition planning must be an integral part of the overall socio-economic development.

**ACTION AT THE INTERNATIONAL LEVEL**

Food and nutrition are global problems, just as health and sickness; and both are interrelated. There is considerable scope for international cooperation in solving the problems of malnutrition. International cooperation can play an important role in mitigating the effects of acute emergencies caused by floods and droughts. The establishment of the multilateral World Food Programme in 1963 to stimulate and promote economic and social development as a means of providing enough safe food to those in need and to come to the aid of victims of emergency is an example of international cooperation. Several international agencies such as the FAO, UNICEF, WHO, World Bank, UNDP, and CARE are working in close collaboration helping the national governments in different parts of the world in their battle against malnutrition.

**FOOD SURVEILLANCE**

Food surveillance is essential for the protection and maintenance of community health. Broadly it implies the monitoring of food safety/food hygiene. The WHO (142) has defined food safety/food hygiene as “all conditions and measures that are necessary during the production,
The primary aim of food hygiene is to prevent food journey from the producer to the consumer. Food hygiene, in its widest sense, implies hygiene in the production, handling, distribution and serving of all types of food (144). The primary aim of food hygiene is to prevent food poisoning and other food-borne illnesses. Food hygiene can be grouped under the following headings:

FOOD HYGIENE

Food is a potential source of infection and is liable to contamination by microorganisms, at any point during its journey from the producer to the consumer. Food hygiene, in its widest sense, implies hygiene in the production, holding, distribution and serving of all types of food (144). The primary aim of food hygiene is to prevent food poisoning and other food-borne illnesses. Food hygiene can be grouped under the following headings:

MILK HYGIENE

Source of Infection

Milk is an efficient vehicle for a great variety of disease agents. The sources of infection or contamination of milk may be (1) the dairy animal (2) human handler or (3) the environment, e.g., contaminated vessels, polluted water, flies, dust, etc. (145).

Milkborne diseases

1. Infections of animals that can be transmitted to man:

Primary importance:
- Tuberculosis
- Brucellosis
- Streptococcal infections
- Staphylococcal enterotoxin poisoning
- Salmonellosis
- Q fever

Lesser importance:
- Cow-pox
- Foot and mouth disease
- Anthrax
- Leptospirosis
- Tick-borne encephalitis

2. Infections primary to man that can be transmitted through milk:

- Typhoid and paratyphoid fevers
- Shigellosis
- Cholera
- Enteropathogenic Escherichia coli (EEC)
- Non-diarrhoeal diseases
  - (a) Streptococcal infections
  - (b) Staphylococcal food poisoning
  - (c) Diphteria
  - (d) Tuberculosis
  - (e) Enteroviruses
  - (f) Viral hepatitis

Clean and safe milk

The safety and keeping quality of milk are related to its microbial content. The first essential in the production of clean and safe milk, therefore, is a healthy and clean animal. Milk from a healthy udder contains only a few organisms, and these are relatively unimportant. Secondly, the premises where the animal is housed and milked should be sanitary. The milk vessels must be sterile and kept covered. The water supply must be bacteriologically safe. Milk handler must be free from communicable diseases, and before milking they must wash their hands and arms. Where possible, milking machines must be used. Milk should be cooled immediately to below 10 deg C after it is drawn to retard bacterial growth. In the production of good quality milk, cleanliness of all containers and equipment in which milk is handled is very important.

Methylene blue reduction test: It is an indirect method for detection of microorganisms in milk. The test is carried out on the milk accepted for pasteurization. It is based on the observation that bacteriae growing in milk bring about a decrease in the colour imparted to milk. In conducting the test, definite quantities of methylene blue are added to 10 ml of milk and the sample is held at a uniform temperature of 37 deg C until the blue colour has disappeared. The milk which remains blue the longest is considered to be of the best quality and a scale of grading different milk samples, on the basis of the time required to reduce a definite quantity of methylene blue has been worked out. The test thus serves as confirmation of heavy contamination and compared with direct counts of bacteriae, it saves time and money.

Pasteurization of milk

Pasteurization may be defined as the heating of milk to such temperatures and for such periods of time as are required to destroy any pathogens that may be present while causing minimal changes in the composition, flavour and nutritive value (WHO, 1970) (146). There are several methods of pasteurization. Three are widely used:

1. Holder (Vat) method: In this process, milk is kept at 63-66 deg C for at least 30 minutes, and then quickly cooled to 5 deg C. This method is recommended for small and rural communities. In larger cities, it is going out of use.

2. HTST method: Also known as "High Temperature and Short Time Method". Milk is rapidly heated to a temperature of nearly 72 deg C, is held at that temperature for not less than 15 seconds, and is then rapidly cooled to 4 deg C. This is now the most widely used method. Very large quantities of milk per hour can be pasteurized by this method.

3. UHT Method: Also known as "ultra-high temperature method." Milk is rapidly heated usually in 2 stages (the second stage usually being under pressure) to 125 deg C for a few seconds only. It is then rapidly cooled and bottled as quickly as possible.

Pasteurization is a preventive measure of public health importance and corresponds in all respects to the modern principles of supplying safe milk. Pasteurization kills nearly 90 per cent of the bacteria in milk including the more heat-resistant tubercle bacillus and the Q fever organisms. But it will not kill thermodynamic bacteria nor the bacterial spores. Therefore, despite pasteurization, with subsequent rise in temperature, the bacteria are bound to multiply. In order to check the growth of microorganisms, pasteurized milk is rapidly cooled to 4 deg C. It should be kept cold until it reaches the consumer. Hygienically produced pasteurized milk has a keeping quality of not more than 8 to 12 hours at 18 deg C.
Tests of pasteurized milk

(1) Phosphatase test: This test is widely used to check the efficiency of pasteurization. The test is based on the fact that raw milk contains an enzyme called phosphatase which is destroyed on heating at a temperature which corresponds closely with the standard time and temperature required for pasteurization. At 60 deg C for 30 minutes phosphatase is completely destroyed. Consequently, the test is used to detect inadequate pasteurization or the addition of raw milk. (2) Standard plate count: The bacteriological quality of pasteurized milk is determined by the standard plate count. Most countries in the West enforce a limit of 30,000 bacterial count per ml of pasteurized milk. (3) Coliform count: Coliform organisms are usually completely destroyed by pasteurization, and therefore, their presence in pasteurized milk is an indication either of improper pasteurization or post-pasteurization contamination. The standard in most countries is that coliforms be absent in 1 ml of milk.

MEAT HYGIENE

The term “meat” includes various tissues of animal origin. The diseases which may be transmitted by eating unwholesome meat are: (1) TAPEWORM INFESTATIONS: Taenia solium, T. saginata, Trichinella spiralis and Fasciola hepatica. (2) BACTERIAL INFECTIONS: anthrax, actinomycosis, tuberculosis and food poisoning.

Meat inspection

Animals intended for slaughter are subjected to proper ante mortem and post mortem inspection by qualified veterinary staff. The principal causes of antemortem rejection of animals are emaciation, exhaustion, pregnancy, sheep-pong, foot-rot, actinomycosis, brucellosis, febrile reactions, etc. The main causes of the post mortem rejection are cysticercus bovis, liver fluke, abscesses, sarcocystis, hydatidosis, septicaemia, parasitic and nodular infections of liver and lungs, tuberculosis, cysticercus cellulose, etc. (147). The characteristics of good meat are that it should be neither pale pink nor a deep purple tint, firm and elastic to touch, should not be slimy and have an agreeable odour.

Slaughter houses

Slaughter houses are the places where animals, whose flesh is intended for human consumption, are killed. The hygiene of the slaughter house is of paramount importance to prevent the contamination of meat during the process of dressing. The following minimum standards for slaughter houses have been suggested under the Model Public Health Act (1955) in India (148). (1) Location: Shall not be near any accumulation of filth or open drain, stable, manure pit and other sources of nuisances. (2) Floors: To be higher than the adjoining land, and shall provide accommodation for the circulation of air are necessary. (4) Kitchen: (a) Floor space minimum 60 sq. ft. (b) Window opening to be 25 per cent of floor area. (5) Storage of cooked food: Separate room to be provided. (6) Storage of uncooked foodstuffs: Perishable and non-perishable articles to be kept separately, in rat-proof and

FISH

Fish deteriorates or loses its freshness because of autolysis which sets in after death and because of the bacteria with which they become infected. Stale fish should be condemned. The signs of fresh fish are: (1) It is in a state of stiffness or rigor mortis, (2) the gills are bright red, and (3) the eyes are clear and prominent.

Fish is the intermediate host of the tape worm, Dibothriocephalus latus. This cestode is communicable to man, but is very rarely encountered. Sewage, bacteria and viruses (e.g., the virus of hepatitis type A) may be concentrated in shellfish such as oysters, and fish may carry Vibrio parahaemolyticus, Salmonella spp., Clostridium botulinum type E, and other organisms (149). Consumption of certain fish may sometimes give rise to 'fish poisoning'.

TINNED FISH: When called upon to inspect tinned fish (or meat or any food), the following points should be noted: the tin must be new and clean without leakages or rusting; there should be no evidence of having been tampered with such as sealed openings; on opening the tin, the contents should not be blown out which indicates decomposition.

FRUITS AND VEGETABLES

Fruits and vegetables constitute another important source for the spread of pathogenic organisms, protozoans and helminths. These infections are a serious menace to public health where sewage is used for growing vegetables. The vegetables which are consumed raw in the form of salads pose a problem in food sanitation. People should be educated to wash the vegetables before eating them raw. Vegetables which are cooked are free from this danger.

Sanitation of eating places

Sanitation of eating establishments is a challenging problem in food sanitation. The following minimum standards have been suggested for Restaurants and Eating Houses in India under the Model Public Health Act (1955) (148). (1) Location: Shall not be near any accumulation of filth or open drain, stable, manure pit and other sources of nuisances. (2) Floors: To be higher than the adjoining land, made with impervious material and easy to keep clean. (3) Rooms: (a) Rooms where meals are served shall not be less than 100 sq. feet and shall provide accommodation for a maximum of 10 persons. (5) Walls up to 3 feet should be smooth, corners to be rounded; should be impervious and easily washable. (c) Lighting and ventilation — ample natural lighting facilities aided by artificial lighting with good circulation of air are necessary. (4) Kitchen: (a) Floor space minimum 60 sq. ft. (b) Window opening to be 25 per cent of floor area. (c) Floor to be impervious, smooth, easy to keep clean and non-slippery. (d) Doors and windows to be rat-proof, fly-proof, and of the self-closing type. (e) Ventilators 2 per cent of the floor area in addition to smoke pipes. (5) Storage of cooked food: Separate room to be provided. (6) Storage of uncooked foodstuffs: Perishable and non-perishable articles to be kept separately, in rat-proof and

EGG

Although the majority of freshly laid eggs are sterile inside, the shells become contaminated by faecal matter from the hen. Microorganisms including pathogenic Salmonella can penetrate a cracked shell and enter the egg (149).
vermin-proof space; for storage of perishable articles temperature control should be adopted. (7) Furniture: Should be reasonably strong and easy to keep clean and dry. (8) Disposal of refuse: To be collected in covered, impervious bins and disposed off twice a day. (9) Water supply: To be an independent source, adequate, continuous and safe. (10) Washing facilities: To be provided. Cleaning of utensils and crockery to be done in hot water and followed by disinfection.

**Food handlers**

Food sanitation rests directly upon the state of personal hygiene and habits of the personnel working in the food establishments. Proper handling of foods, utensils and dishes together with emphasis upon the necessity for good personal hygiene are of great importance. The infections which are likely to be transmitted by the food handlers are diarrhoeas, dysenteries, typhoid and paratyphoid fevers, enteroviruses, viral hepatitis, protozoal cysts, eggs of helminths, streptoc and staphylococcal infections, and salmonellosis.

The first essential is to have complete medical examination carried out of all food handlers at the time of employment. Any person with a history of typhoid fever, diphtheria, chronic dysentery, tuberculosis or any other communicable disease should not be employed. Persons with wounds, cutis media or skin infections should not be permitted to handle food or utensils. The day to day health appraisal of the food handlers is also equally important; those who are ill should be excluded from food handling. It is also important that any illness which occurs in a food handler's family should at once be notified.

Education of food handlers in matters of personal hygiene, food handling, utensils washing, and insect and rodent control is the best means of promoting food hygiene. Many of the food handlers have little educational background. Certain aspects of personal hygiene are therefore required to be continually impressed upon them:

(a) Hands: The hands should be clean at all times. Hands should be scrubbed and washed with soap immediately after visiting a lavatory and as often as necessary at other times. Finger nails should be kept trimmed and free from dirt.

(b) Hair: Head coverings should be provided, particularly in the case of females to prevent loose hair entering the food-stuffs.

(c) Overalls: Clean white overalls should be worn by all food handlers.

(d) Habit: Coughing and sneezing in the vicinity of food, licking the fingers before picking up an article of food, smoking on food premises are to be avoided.

**FOOD-BORNE DISEASES**

The term "food-borne disease" is defined as: "A disease, usually either infectious or toxic in nature, caused by agents that enter the body through the ingestion of food." With the increase in urbanization, industrialization, tourism and mass catering systems, food-borne diseases are on the increase throughout the world. Food-borne diseases may be classified as:

**A. Food-borne intoxications**

1. Due to naturally occurring toxins in some foods (150):
   a. Lathyrism (beta oxalyl amino-alanine)
   b. Endemic ascitis (Pyrolizidine alkaloids)

2. Due to toxins produced by certain bacteria (130, 151):
   a. Botulism
   b. Staphylococcus poisons

3. Due to toxins produced by some fungi (149, 152):
   a. Aflatoxin
   b. Ergot
   c. Fusarium toxins

4. Food-borne chemical poisoning (153, 154):
   a. Heavy metals, e.g., mercury (usually in fish), cadmium (in certain shellfish) and lead (in canned food)
   b. Oils, petroleum derivatives and solvents (e.g., Trycresyn phosphate or TCP)
   c. Migrant chemicals from package materials
   d. Asbestos
   e. Pesticide residues (DDT, BHC)

**B. Food-borne infections**

</tr>
</tbody>
</table>

**FOOD TOXICANTS**

1. **Neurolathyrism**

The cause of neurolathyrism is a toxin, Beta oxalyl amino alanine (BOAA) which is found in the seeds of the pulse, *L. sativus* (Khesari dhal). Neurolathyrism is a public health problem in certain parts of the country where this pulse is eaten (see page 701).

2. **Aflatoxins** (155, 156)

Aflatoxins are a group of mycotoxins produced by certain fungi, *Aspergillus flavus* and *A. parasiticus*. These fungi infect food grains such as groundnut, maize, parboiled rice, sorghum, wheat, rice, cotton seed and tapioca under conditions of improper storage, and produce aflatoxins of which *B. G* and *G* are the most potent hepatotoxins, in addition to being carcinogenic. The most important factors affecting the formation of the toxine are moisture and temperature. Moisture levels above 16 per cent and temperatures ranging from 11 to 37°C favour toxin formation. Aflatoxicosis is quite a public health problem in India. The latest report (1975) of 400 cases of aflatoxin poisoning including 100 deaths from Banswada and Panchmahal districts of Rajasthan and Gujarat respectively highlight the problem in India. Aflatoxin B has also been detected in samples of breast milk and urine collected from children suffering from infantile cirrhosis. Attempts are also being made to relate aflatoxin with human liver cirrhosis.
Control and preventive measures: A crucial factor in the prevention of fungal contamination of foodgrains is to ensure their proper storage after drying. Moisture content should be kept below 10 per cent. If the food is contaminated, it must not be consumed. It is also essential to educate the local population on the health hazards of consuming contaminated foodgrains.

3. Ergot (157, 158)

Unlike Aspergillus, ergot is not a storage fungus, but a field fungus. Foodgrains such as bajra, rye, sorghum, and wheat have a tendency to get infested during the flowering stages by the ergot fungus (Claviceps purpurea). Fungus grows as a blackish mass and the seeds become black and irregular and are harvested along with food grains. Consumption of ergot-infested grain leads to ergotism. Sporadic outbreaks of ergot poisoning in human population have been reported from time to time in areas where bajra is consumed as a staple. The symptoms are acute but rarely fatal and include nausea, repeated vomiting, giddiness and drowsiness extending sometimes for periods up to 24 to 48 hours after the ingestion of ergot grain. In chronic cases, painful cramps in limbs and peripheral gangrene due to vasoconstriction of capillaries have been reported. However, the long-term effects of consuming small amounts of the toxin are not known. A disquieting feature is that the recently introduced high-yielding varieties of bajra are more susceptible to infestation. Ergot-infested grains can be easily removed by hand-picking or air floatation. The upper safe limit for the ergot alkaloids has been estimated to be 0.05 mg per 100 grams of the food material.

4. Epidemic dropsy (159, 144)

From time to time, outbreaks of "epidemic dropsy" are reported in India. The cause of epidemic dropsy was not known until 1926, when Sarkar ascribed it to the contamination of mustard oil with argemone oil. Lal and Roy (1937) and Chopra et al. (1939) gave experimental proof of the cause of epidemic dropsy. Mulkeri et al. (1941) isolated a toxic alkaloid, sanguinarine from argemone oil and found out its chemical formula. This toxic substance interferes with the oxidation of pyruvic acid which accumulates in the blood.

The symptoms of epidemic dropsy consist of sudden, non-inflammatory, bilateral swelling of legs, often associated with diarrhea. Dyspnea, cardiac failure and death may follow. Some patients may develop glaucoma. The disease may occur at all ages except breast-fed infants. The overall mortality was 40 per cent.

The contamination of mustard or other oils with argemone oil may be accidental or deliberate. Seeds of Argemone mexicana (prickly poppy) closely resemble mustard seeds. The plant grows wild in India. It has prickly leaves and bright yellow flowers. Crops of mustard are gathered during March, and during this period, the seeds of argemone also mature and are likely to be harvested along with mustard seeds. Sometimes unscrupulous dealers mix argemone oil with mustard or other oils.

Argemone oil is orange in colour with an acrid odour. The following tests may be applied for the detection of argemone oil: (1) Nitric acid test: A simple test is to add nitric acid to the sample of oil in a test tube. The tube is shaken and the development of a brown to orange-red colour shows the presence of argemone oil. The nitric acid test is positive only when the level of argemone oil is about 0.25 per cent (160). (2) Paper chromatography test: This is the most sensitive test yet devised. It can detect argemone oil up to 0.0001 per cent in all edible oils and fats.

The accidental contamination of mustard seeds can be prevented at the source by removing the argemone weeds growing among oil-seed crops. Unscrupulous dealers may be dealt with by the strict enforcement of the Prevention of Food Adulteration Act.

5. Endemic ascites (161, 162)

In Kusmi Block of Sarguja district in Madhya Pradesh, during 1973 and again during 1976, an outbreak of rapidly developing ascites and jaundice was reported among the Nagesia tribals. Both the sexes and all the age groups, except infants, were affected. The overall mortality was 40 per cent.

Studies conducted by the National Institute of Nutrition, Hyderabad showed that the local population subsisted on the millet Panicum miliare (known locally as Gondhli) which gets contaminated with weed seeds of Crotalaria (locally known as Jhunjhunia). On chemical analysis, Jhunjhunia seeds were found to contain pyrrolizidine alkaloids which are hepatotoxins.

The preventive measures comprise educating the people in the affected areas about the disease, deweeding of the Jhunjhunia plants which grow along with the staple, and simple sieving of the millet at the household level to remove the seeds of Jhunjhunia which are considerably smaller than those of the millet.

6. Fusarium toxins (163)

Fusarium species of field fungi are known to contaminate food crops and pose health hazards to livestock and man. The problem of fusarium contamination of sorghum is believed to be on the increase. Rice is also known to be a good substrate for fusarium. Work is now in progress at the National Institute of Nutrition to isolate, and identify the toxic metabolites produced by fusarium incarnatum.

Food additives

The concept of adding "non-food" substances to food products is not new. Pickling is an ancient culinary practice aimed at preserving food articles such as mango, lime, etc for fairly long periods by the addition of salt and spices. Modern science of food technology has revolutionized food processing with the introduction of chemical additives to increase the shelf-life of food, improve its taste, and to change its texture or colour. Majority of the processed foods such as bread, biscuits, cakes, sweets, confectionary, jams, jellies, soft drinks, ice creams, ketchup and refined oils contain food additives.

Food additives are defined as non-nutritious substances which are added intentionally to food, generally in small quantity, to improve its appearance, flavour, texture or storage properties (164). This definition also includes animal food adjuncts which may result in residues in human food and components of packing materials which may find their way into food (165).

Food additives may be classified into two categories: Additives of the first category include colouring agents (e.g., saffron, turmeric), flavouring agents (e.g., vanilla essence), sweeteners (e.g., saccharin), preservatives (e.g.,
sorbic acid, sodium benzoate), acidity imparting agents (e.g., citric acid, acetic acid), etc (166). These agents are generally considered safe for human consumption. Additives of the second category are, strictly speaking, contaminants incidental through packing, processing steps, farming practices (insecticides) or other environmental conditions (167). Uncontrolled or indiscriminate use of food additives may pose health hazards among consumers. For example, certain preservatives such as nitrates and nitrites can lead to the production of toxic substances, e.g., nitrosamines that have been implicated in cancer aetiology.

The use of food additives is subjected to government regulations throughout the world. In India two regulations (viz. the Prevention of Food Adulteration Act and the Fruit Products Order) govern the rules and regulations of food additives (167). Any food that contains food additives that are not permitted is considered to be adulterated; if the permissible limit exceeds then also the food is considered adulterated. The nature and quantity of the additive shall be clearly printed on the label to be affixed to the container. Whenever, any extraneous colouring matter has been added to any article of food, the words “Artificially Coloured” shall be written on the label. At the international level, in 1963, a joint FAO/WHO programme on food standards was established, with the FAO/WHO Codex Alimentarius Commission as its principal organ. Protection of the health of consumers is the primary aim of the Commission. The ultimate effects of food additives on mankind is an important problem of public health and is therefore of great concern to the public and the health administrators.

**Food fortification**

Fortification of food is a public health measure aimed at supplementing the usual dietary intake of nutrients with additional supplies to prevent/control some nutritional disorders. WHO (1) has defined “food fortification” as “the process whereby nutrients are added to foods (in relatively small quantities) to maintain or improve the quality of the diet of a group, a community, or a population.”

Programmes of demonstrated effectiveness of fortification of food or water are: fluoridation of water as a preventive of dental caries; iodization of salt for combating the problem of endemic goitre, and food fortification (e.g., vanaspati, milk) with vitamins A and D. Technology has also been developed for the twin fortification of salt with iodine and iron.

In order to qualify as suitable for fortification, the vehicle and the nutrient must fulfil certain criteria (25):

(a) the vehicle fortified must be consumed consistently as part of the regular daily diet by the relevant sections of the population or total population;

(b) the amount of nutrient added must provide an effective supplement for low consumers of the vehicle, without contributing a hazardous excess to high consumers;

(c) the addition of the nutrient should not cause it to undergo any noticeable change in taste, smell, appearance, or consistency; and

(d) the cost of fortification must not raise the price of the food beyond the reach of the population in greatest need.

Finally, an adequate system of surveillance and control is indispensable for the effectiveness of food fortification. Food fortification is a long-term measure for mitigating specific problems of malnutrition in the community.

**Adulteration of foods**

Adulteration of foods is an age-old problem. It consists of a large number of practices, e.g., mixing, substitution, concealing the quality, putting up decomposed foods for sale, misbranding or giving false labels and addition of toxicants. Adulteration results in two disadvantages for the consumer: first, he is paying more money for a foodstuff of lower quality; secondly, some forms of adulteration are injurious to health, even resulting in death, as for example, adulteration of mustard oil with argemone oil causing epidemic dropsy or adulteration of edible oils with trycresyl phosphate (TCP) resulting in paralysis and death.

Food adulteration practices vary from one part of the country to another, and from time to time. Our knowledge about the current practices of food adulteration is by no means complete. Table 35 shows the types of adulteration seen in India (168).

**Prevention of Food Adulteration Act, 1954**

Enacted by the Indian Parliament in 1954, with the objective of ensuring pure and wholesome food to the consumers and to protect them from fraudulent and deceptive trade practices, the Prevention of Food Adulteration (PFA) Act was amended in 1964, 1976 and lately in 1986 to make the Act more stringent. A minimum imprisonment of 6 months with a minimum fine of Rs.1,000 is envisaged under the Act for cases of proven adulteration, whereas for the cases of adulteration which may render the food injurious to cause death or such harm which may amount to grievous hurt (within the meaning of section 320 of I.P.C.) the punishment may go upto life imprisonment and a fine which shall not be less than Rs.5,000. With the amendment in 1986, the consumer and the voluntary organizations have been empowered under the Act to take samples of food.
Rules are framed which are revised from time to time by an expert body called the “Central Committee for Food standards” which is constituted by the Central Government under the provisions of the Act. Any food that does not conform to the minimum standards is said to be adulterated. Although it is a Central Act, its implementation is largely carried out by the State Governments and local bodies in their respective areas. However, the Centre plays a vital role in proper coordination, monitoring and surveillance of the programme throughout the country. A chain of food laboratories and four regional appellate Central Food Laboratories (Kolkata, Mysore, Ghaziabad and Pune) whose report is considered to be final have been established.

Training being an important component of the programme for prevention of food adulteration, the Directorate General of Health Services organizes in-service training programme for different functionaries responsible for implementation of the PFA Act. Food inspectors, analysts and the senior officers concerned with the implementation of the Act in States are provided training.

Food adulteration is a social evil. The general public, traders, and Food Inspectors are all responsible for perpetuating this evil – the public, because of lack of awareness of the dangers of adulteration and their general disinterest; the traders, for their greed for money, and Food Inspectors who find food adulteration fertile ground to make easy money. Unless the public rises up against the traders and unscrupulous food inspectors, this evil cannot be curbed. It is here the voluntary agencies and consumer guidance societies can play a vital role.

Food standards

(a) CODEX ALIMENTARIUS : The Codex Alimentarius Commission, which is the principal organ of the joint FAO/WHO Food Standards Programme formulates food standards for international market. The food standards in India are based on the standards of the codex alimentarius.

(b) PFA STANDARDS : Under the Prevention of Food Adulteration Act (1954) standards have been established which are revised from time to time by the “Central Committee for Food Standards”. The purpose of the PFA standards is to obtain a minimum level of quality of foodstuffs attainable under Indian conditions. (c) THE AGMARK STANDARDS : These standards are set by the Directorate of Marketing and Inspection of the Government of India. The Agmark gives the consumer an assurance of quality in accordance with the standards laid down. (d) BUREAU OF INDIAN STANDARDS : The ISI mark on any article of food is a guarantee of good quality in accordance with the standards prescribed by the Bureau of Indian Standards for that commodity. The Agmark and ISI standards are not mandatory; they are purely voluntary. They express degrees of excellence above PFA standards.

National Nutrition Policy 1993 (169)

Insipite of the significant improvement in food production and advancement in science since independence, under-nutrition continues to be a widespread problem in India. In the year 1993, Govt. of India announced National Nutrition Policy 1993. As nutrition is a multi-sectoral issue, it needs to be tackled at various levels through direct nutrition interventions for specifically vulnerable groups as well as through various development policy instruments which will create conditions for improved nutrition. The strategy consists of the following:

A. Direct intervention – Short-term

1. Nutrition interventions for specially vulnerable groups.
   a. Expanding the Safety Net – The universal immunization programme, oral rehydration therapy and the integrated child development services have a considerable impact on child survival and extreme forms of malnutrition.
   b. Improving growth monitoring between age group 0 to 3 years, with closer involvement of the mothers.
   c. Reaching the adolescent girls through ICDS so as to make them ready for safe motherhood.
   d. Ensuring better coverage of expectant women in order to reduce the incidence of low birth weight babies.

2. Fortification of essential foods.
3. Popularization of low cost nutritious food.
4. Control of micro-nutrient deficiencies among vulnerable groups.

B. Indirect Policy Instruments : Long-term Institutional and structural changes

1. Food security – In order to ensure aggregate food security, a per capita availability of 215/kg/person/ year of food grain needs to be attained.
2. Improvement of dietary pattern through production and demonstration.
3. Improving the purchasing power of the urban and rural poor and improving the public food distribution system.
4. Land reforms.
5. Health and family welfare.
6. Basic health and nutrition knowledge.
10. Research into various aspects of nutrition, both on the consumption side and the supply side.
11. Equal remuneration for women.
12. Communication through established media for the implementation of nutrition policy.
13. Minimum wage administration.
15. Education and literacy particularly that of women.
16. Improvement of the status of women.

COMMUNITY NUTRITION PROGRAMMES

The Government of India have initiated several large-scale supplementary feeding programmes, and programmes aimed at overcoming specific deficiency diseases through various Ministries to combat malnutrition. They are as shown in Table 36.
1. Vitamin A prophylaxis programme

One of the components of the National Programme for Control of Blindness is to administer a single massive dose of an oily preparation of vitamin A containing 200,000 IU (110 mg of retinol palmitate) orally to all pre-school children in the community every 6 months through peripheral health workers. This programme was launched by the Ministry of Health and Family Welfare in 1970 on the basis of technology developed at the National Institute of Nutrition at Hyderabad. An evaluation of the programme has revealed a significant reduction in vitamin A deficiency in children (see page 672, 673 for details).

2. Prophylaxis against nutritional anaemia

In view of its public health importance, a national programme for the prevention of nutritional anaemia was launched by the Govt. of India during the fourth Five Year Plan. The programme consists of distribution of iron and folic acid (folifar) tablets to pregnant women and young children (1-12 years). Mother and Child Health (MCH) Centres in urban areas, primary health centres in rural areas and ICDS projects are engaged in the implementation of this programme. The technology for the control of anaemia through iron fortification of common salt has also been developed at the National Institute of Nutrition at Hyderabad (see page 699 for more details).

3. Control of iodine deficiency disorders

The National Goitre Control Programme was launched by the Government of India in 1962 in the conventional goitre belt in the Himalayan region with the objective of identification of the goitre endemic areas to supply iodized salt in place of common salt and to assess the impact of goitre control measures over a period of time.

Surveys, however, indicated that the problem of goitre and iodine deficiency disorders was more widespread than it was thought earlier, with nearly 145 million people estimated to be living in known goitre endemic areas of the country. As a result, a major national programme – the IDD Control Programme – was mounted in 1986 with the objective to replace the entire edible salt by iodide salt, in a phased manner by 1992 (see page 700 for more details).

4. Special nutrition programme

This programme was started in 1970 for the nutritional benefit of children below 6 years of age, pregnant and nursing mothers and is in operation in urban slums, tribal areas and backward rural areas. The supplementary food supplies about 300 kcal and 10-12 grams of protein per child per day. The beneficiary mothers receive daily 500 kcal and 25 grams of protein. This supplement is provided to them for about 300 days in a year. This programme was originally launched as a Central programme and was transferred to the State sector in the fifth Five Year Plan as part of the Minimum Needs Programme (170). The main aim of the Special Nutrition Programme is to improve the nutritional status of the target groups. This programme is gradually being merged into the ICDS programme.

5. Balwadi nutrition programme

This programme was started in 1970 for the benefit of children in the age group 3–6 years in rural areas. It is under the overall charge of the Department of Social Welfare. Four national level organizations including the Indian Council of Child Welfare are given grants to implement the programme. Voluntary organizations which receive the funds are actively involved in the day-to-day management. The programme is implemented through Balwadis which also provide pre-primary education to these children. The food supplement provides 300 kcal and 10 grams of protein per child per day. Balwadis are being phased out because of universalization of ICDS.

6. ICDS programme

Integrated Child Development Services (ICDS) programme was started in 1975 in pursuance of the National Policy for Children. There is a strong nutrition component in this programme in the form of supplementary nutrition, vitamin A prophylaxis and iron and folic acid distribution. The beneficiaries are preschool children below 6 years, and adolescent girls 11 to 18 years, pregnant and lactating mothers. The States and Union Territories are encouraged to undertake additional ICDS projects on the Central pattern to cover more beneficiaries (170).

The workers at the village level who deliver the services are called Anganwadi workers. Each Anganwadi unit covers a population of about 400 to 800 and mini Anganwadi centre about 150 to 400. A network of Mahila Mandal has been built up in ICDS Project areas to help Anganwadi workers in providing health and nutrition services. The work of Anganwadis is supervised by Mukhyasevikas. Field supervision is done by the Child Development Project Officer (CDPO).

7. Mid-day meal programme

The mid-day meal programme (MDMP) is also known as School Lunch Programme. This programme has been in operation since 1961 throughout the country. The major objective of the programme is to attract more children for admission to schools and retain them so that literacy improvement of children could be brought about (169).

In formulating mid-day meals for school children, the following broad principles should be kept in mind (171):

(a) the meal should be a supplement and not a substitute to the home diet;
(b) the meal should supply at least one-third of the total energy requirement, and half of the protein need;
(c) the cost of the meal should be reasonably low;
(d) the meal should be such that it can be prepared easily in schools; no complicated cooking process should be involved.
(e) as far as possible, locally available foods should be used; this will reduce the cost of the meal; and
(f) the menu should be frequently changed to avoid monotony.

MODEL MENU
A model menu for a mid-day school meal is given in Table 37.

The National Institute of Nutrition, Hyderabad has prepared model recipes for the preparation of school meals suitable for North and South Indians. Copies of these publications can be had gratis on request. The National Institute of Nutrition is of the view that the minimum number of feeding days in a year should be 250 to have the desired impact on the children (172).

School feeding should not be considered as an end in itself. The important goals to be accomplished are: reorientation of eating habits; incorporating nutrition education into the curriculum; encouraging the use of local commodities; improving school attendance as well as educational performance of the pupils. Since the number to be fed are in millions, the problem is one of balance between the resources and the number to be fed.

The mid-day meal programme became part of the Minimum Needs Programme in the Fifth Five Year Plan (170).

8. Mid-day meal scheme (173)
Mid-day meal scheme is also known as National Programme of Nutritional Support to Primary Education. It was launched as a centrally sponsored scheme on 15th August 1995 and revised in 2004. Its objective being universalization of primary education by increasing enrolment, retention and attendance and simultaneously impacting on nutrition of students in primary classes. It was implemented in 2,408 blocks in the first year and covered the whole country in a phased manner by 1997-98. The programme originally covered children of primary stage (classes I to V) in government, local body and government aided schools and was extended in Oct. 2002, to cover children studying in Education Guarantee Scheme and Alternative and Innovative Education Centres also.

The central assistance provided to states under the programme is by way of free supply of food grain from nearest Food Corporation of India godown at the rate of 100 g. per student per day and subsidy for transport of food grain. To achieve the objective, a cooked mid-day meal with minimum 300 Calories and 8 to 12 grammes of protein content will be provided to all the children in class I to V.

Some suggestions for preparation of nutritious and economical mid-day meals are as under:
- Foodgrains must be stored in a place away from moisture, in air tight containers/bins to avoid infestation.
- Use whole wheat or broken wheat (dalia) for preparing mid-day meals.
- Rice should preferably be parboiled or unpolished.
- ‘Single Dish Meals’ using broken wheat or rice and incorporating some amount of a pulse or soyabeans, a seasonal vegetable/green leafy vegetable, and some amount of edible oil will save both time and fuel besides being nutritious. Broken wheat pulao, leafy khichuri, upma, dal-vegetable bhaat are some examples of single dish meals.
- Cereal pulse combination is necessary to have good quality protein. The cereal pulse ratio could range from 3:1 to 5:1.
- Sprouted pulses have more nutrients and should be incorporated in single dish meals.
- Leafy vegetables when added to any preparation should be thoroughly washed before cutting and should not be subjected to washing after cutting.
- Soaking of rice, dal, bengal gram etc. reduces cooking time. Wash the grains thoroughly and soak in just sufficient amount of water required for cooking.
- Rice water if left after cooking should be mixed with dal if these are cooked separately and should never be thrown away.
- Fermentation improves nutritive value. Preparation of idli, dosa, chokla etc. may be encouraged.
- Cooking must be done with the lid on to avoid loss of nutrients.
- Over cooking should be avoided.
- Reheating of oil used for frying is harmful and should be avoided.
- Leafy tops of carrots, radish, turnips etc. should not be thrown away but utilized in preparing mid-day meals.
- Only ‘iodized salt’ should be used for cooking mid-day meals.

**Monitoring and evaluation of nutrition programmes**

Good preventive medicine demands effective planning, monitoring and evaluation of health programmes. An important advance in this field is the development of the randomized controlled trial for the evaluation of the effectiveness and efficiency of health care programmes.

Criticism is often voiced that nutrition programmes are not based on good intentions. It is considered unethical to launch a major nutritional programme (or for that matter any other health programme) without a built-in-provision for monitoring, evaluation and feedback.

Since health and nutrition of the young child is indivisible from the health and nutrition of the family as a whole, there is now increasing recognition that it is only through an improvement of the family diet as a whole, that the diet of the young child in the poor family can be improved (174). Secondly, a question is raised: How long will a country be able to feed its children who may number 100 million or more without any socio-economic improvements? An eminent nutrition scientist in India has said: “In the long run, we can hope to improve the nutritional status of our children only through improvement in the economic conditions of the community to a level at which families can afford balanced diets. Organized State-sponsored feeding programmes cannot be the permanent answer to the problem” (85).

ANNEXURE-5
Exercise and physical activity

Individuals over the age of 20 years should undertake a minimum of 30 minutes of physical activity of moderate intensity (such as walking 5-6 km/hr) on most, if not all days of the week. Greater health benefits can be obtained by engaging in physical activity of longer duration or more vigorous intensity (such as jogging, running, cycling and swimming).

Sedentary people embarking on a physical activity programme should undertake a moderate intensity activity of short duration to start with and gradually increase the duration or intensity. Other day-to-day activities like walking, housework, gardening, will be beneficial not only in weight reduction but also for lowering of blood pressure and serum triglycerides. This also elevates HDL (good) cholesterol in blood. Simple modification in lifestyle like deliberately climbing up the stairs instead of using the lift and walking for short distance instead of using a vehicle could also immensely help in increasing our physical activity.

Exercise programme should include ‘warm up’ and ‘cool down’ periods each lasting for 5 minutes. During exercise, the intensity of exercise should ensure 60-70% increase in heart rate.

Previously inactive men over the age of 40 years, women over the age of 50 years and people at high risk for chronic diseases like heart disease and diabetes should first consult a physician before engaging in a programme of vigorous physical activity such as running and swimming.

- **Samosa** 1 No. 200
- **Sandwich (butter : 2 tsp)*** 2 Nos. 200
- **Vegetable puff** 1 No. 170
- **Pizza (Cheese and tomato)** 1 slice 200

#### 6. Chutneys:
- **Coconut/ground/til** 2 tbsp 120
- **Tomato** 1 tbsp 10
- **Tamarind (with jaggery)** 1 tbsp 60

### Preparation Quantity for Calories one serving (kcal)

#### 7. Sweets and desserts:
- **Besan barfi** 2 pieces 400
- **Chikki** 2 pieces 290
- **Fruit cake** 1 piece 270
- **Rice puttu** 1/2 cup 280
- **Sandesh** 2 Nos. 140
- **Double ka meetha** 1/2 cup 280
- **Halwa (kesari)** 1/2 cup 320
- **Jelly/Jam** 1 tsp 20
- **Custard (caramel)** 1/2 cup 160
- **Srikhand** 1/2 cup 380
- **Milk chocolate** 25 g 140
- **Ice-cream** 1/2 cup 200

#### 8. Beverages:
- **Tea** (2 tsp sugar + 50 ml toned milk) 1 cup 110
- **Coffee** (2 tsp sugar + 10 ml toned milk) 1 cup 110
- **Cow's milk** (2 tsp sugar) 1 cup 180
- **Buffalo's milk** (2 tsp sugar) 1 cup 320
- **Lassi** (2 tsp sugar) 1 glass (200 ml) 110
- **Squash** 1 glass (200 ml) 75
- **Syrahs (Sherbet)** 1 glass (200 ml) 200
- **Cold drinks** 1 bottle (200 ml) 150
- **Fresh lime juice** 1 glass (200 ml) 60

### Nuts:
- **Almonds** 10 Nos. 65
- **Cashewnuts** 10 Nos. 95
- **Coconut (fresh)** 1/4 130
- **Coconut (dry)** 1/4 140
- **Peanuts** 50 Nos. 90

### Fresh fruits:
- **Apple** 1 medium 65
- **Banana** 1 medium 90
- **Grapes** 30 Nos. 70
- **Guava** 1 medium 50
- **Jackfruit** 4 pieces 90
- **Mango** 1 medium 180
- **Mosambi/orange** 1 medium 40
- **Papaya** 1 piece 80
- **Pineapple** 1 piece 50
- **Sapota** 1 medium 80
- **Custard apple** 1 medium 130
- **Watermelon/musk melon** 1 slice 15

### Salads:
- **Beetroot** 1 medium 30
- **Carrot** 1 medium 20
- **Cucumber** 1 medium 15
- **Onion** 1 medium 25
- **Radish** 1 medium 10
- **Tomato** 1 medium 10

<td>From foods</td>
</tr>
</tbody>
</table>

a. This is calculated as: total fat - (saturated fatty acids + polyunsaturated fatty acids + trans-latty- acids).
b. The percentage of total energy available after taking into account that consumed as protein and fat, hence the wide range.
c. The term “free sugars” refers to all monosaccharides and disaccharides added to foods by the manufacturer, cook or consumer, plus sugars naturally present in honey, syrups and fruit juices.
d. The suggested range should be seen in the light of the Joint WHO/FAO/UNU Expert Consultation on Protein and Amino Acid Requirements in Human Nutrition, held in Geneva from 9 to 16 April 2002.
e. Salt should be iodized appropriately. The need to adjust salt intake, depending on observed sodium intake and surveillance of iodine status of the population, should be recognized.

The term "social sciences" refers to a composite of several disciplines. These disciplines are anthropology, economics, political science, psychology, sociology etc. In general, these disciplines contribute to our understanding of society and human behaviour. The social sciences relevant to medicine are psychology and sociology. They should be considered like anatomy and physiology, the basic sciences of medicine.

Social context of medicine

Health cannot be isolated from its social context. The last few decades have shown that social and economic factors have as much influence on health as medical interventions. All these factors have a direct bearing on the incidence, course and outcome of a wide variety of communicable and non-communicable diseases as well as on many other health problems besetting the world today. They also have an important effect on the provision of health care to all strata of society. Poverty, malnutrition, poor sanitation, lack of education, inadequate housing, unemployment, poor working conditions, cultural and behavioural factors all predispose to ill-health. Today more than ever before, there has been an increasing recognition that successful application of medicine to individuals and groups involves more than mere scientific or biological knowledge; it involves an understanding of the behaviour of individuals and groups who live together and also share certain values of life. Man is a social animal. The patient is no longer considered as one who is under strict laboratory control, but an individual with personal idiosyncrasies, erratic habits, customs and beliefs reacting on his body and mind. It has been aptly said that even a person with a broken leg may present complex social and personal factors which may influence his recovery. Thus there has been a shift from the earlier concept of visualizing disease in terms of a specific germ to the involvement of "multiple factors" in the causation of disease. Good doctors are being identified as those who treat people, and bad ones as those who treat cases. As a result of this new outlook, concepts of sociology are increasingly being used in the study of disease in human societies.

How much effect social changes might have on health of the people is shown in Fig. 1.

It suggests that health is influenced by four sets of variables— individual predispositions, ecological predispositions, current circumstances, and opportunities. These variables are in turn influenced by the major sources of social changes: economic, political, educational and other systems. The health status of the people can feed back into and influence factors relating to social structure which may in turn influence the predisposing variables, and therefore health.

Medicine and the social sciences are concerned, in their own special way, with human behaviour. Specialists in community health, clinical medicine, epidemiology are all seeking the cooperation and help of social scientists in understanding problems such as the social component of health and disease, "illness behaviour" of people, efficient use of medical care and the study of medical institutions. A brief sketch of the current interest of these disciplines in social science is given below:

1. COMMUNITY HEALTH

Community health workers are often faced with the problem of why people who need a particular service are least likely to use it or fail to secure the total benefit which is expected. A case in point is immunization against communicable diseases. Although, there is a wide range of prophylactic vaccines, immunization has not gained universal acceptance. The family planning programme in India is a recent example of a health service of which people are not making use to the extent desired. Similarly, health programmes relating to mother and child health care services, improvement of water supplies, installation of sanitary latrines, improvement of dietary patterns and infant rearing practices have all proved abortive or only partially successful. The resistance of the people is felt not only in the field of community health, but in fact even in fields designed to improve their general standard of living. The central question in community health is: Why do people behave as they do? This is the basic problem which the social scientists are studying in India, and are often asked to explain this failure of health measures. In the western countries, social scientists are working on problems of mental health, hospital organization, social class difference in disease, rehabilitation, and professional roles and relationships. In industries, the social scientists are invited to look into the relationships between members of a team who are concerned with doing a job in order to improve the overall performance of the work team. In short, the social scientists are stepping in increasing numbers into the field of community health. The theme common to community health and social sciences is human behaviour. Many community health problems in essence are social problems, and vice versa.

2. CLINICAL MEDICINE

During the past half century, the scientific content of medicine has increased enormously. The acute
Communicable diseases have been brought under control, and good medical care is available to more people than ever before. This has brought to a sharp focus, the so-called "modern diseases" such as cardiovascular disease, cancer, diabetes and mental illness. These diseases have defied "cure" and prevention, and are currently the major causes of morbidity and mortality in developed societies. The clinicians also tend to believe that "psychophysiological stress reactions" are involved in cases of rheumatoid arthritis, obesity, ulceration of intestine, skin diseases, constipation, diarrhea and epilepsy. It has become apparent that control of these diseases involves not merely medical care but basic changes in the behaviour and habits of the patients, which is a field of specialization of social scientists. The social scientists are asked to investigate the life situations of the patients with a view to discover linkages between specific life situations and specific types and cases of illness.

The clinicians have also shown interest in what is known as "illness behaviour" of patients, i.e., why different people react in different ways to the same disease process or regimen of treatment. It is not known why some people (whether by reason of education, religion, social class difference or occupational status) make light of symptoms and some respond in an exaggerated manner, to the slightest pain or discomfort. This is an important area of medical sociology. The doctor-patient relationship, patient care management, hospital organization, collusion of medical treatment and cultural practices are all current interests of medical sociology.

Criticism is often voiced that the present medical sciences (e.g., anatomy, physiology, microbiology, pathology) are insufficient to train the physician to cope with the socio-cultural aspects of medicine. It is recognized that the physician needs two kinds of knowledge - medical knowledge and social knowledge, so that he could more effectively serve the patient and the community. Hence is the current interest of medical men in social sciences.

3. EPIDEMIOLOGY

Epidemiologists have also forged a close alliance with social scientists in studying the distribution of health and disease in human population, and of factors that cause the distribution. Disease is studied in relationship to factors such as social status, income, occupation, housing, overcrowding, social customs, habits and behaviour. Examples can be found in researches into the ecology of coronary heart disease, duodenal ulcer, schizophrenia, mental subnormality, suicide, accidents, and several other conditions.

To sum up, social scientists are studying a great many things of considerable interest to medicine and public health. They have "given fruitful attention to the growing place of medicine and medical practice in the social system, and to different attitudes and values which various segments of the population have towards health, illness and medical care. They have made noteworthy advances in mapping out the social organization of health personnel; the social structure and functioning of hospitals have been studied to advantage, as have the social roles played by patients and health personnel as they interact in different settings. They have paid particular attention to the situation of health personnel who are professionals, and to the social processes through which these persons acquire the outlook, standards and competence considered necessary for providing satisfactory professional services. They have also undertaken investigations which relate various social and psychological factors to different kinds of diseases in patients as well as to the course of certain diseases" (3).
SOCIAL AND BEHAVIOURAL SCIENCES

Medicine and social sciences are concerned in their own special way with human behaviour. The term 'social sciences' is applied to those disciplines which are committed to the scientific examination of human behaviour. These are economics, political science, sociology, social psychology and social anthropology. The term 'behavioural sciences' is applied to the last three, i.e., sociology, social psychology and social anthropology, because they deal directly with human behaviour. Each of these disciplines, while sharing the major goals of social sciences, i.e., the scientific examination of human behaviour deals with specific aspects of public health in the study of man.

(a) ECONOMICS

The field of economics has a very close relationship with sociology. It is the parent discipline from which sociology has emerged. Economics deals with human relationships in the specific context of production, distribution, consumption and ownership of scarce resources, goods and services. Sociology and economics overlap in many senses; both are concerned with interdependence in human relations.

(b) POLITICAL SCIENCE

Historically economics and political science tended to be a single discipline. As a separate discipline, political science is concerned with the study of the system of laws and institutions which constitute government of whole societies.

(c) SOCIOLOGY

Sociology deals with the study of human relationships and of human behaviour for a better understanding of the pattern of human life. It is also concerned with the effects on the individual of the ways in which other individuals think and act.

(d) SOCIAL PSYCHOLOGY

This discipline sprang from psychology. It is concerned with the psychology of individuals living in human society or groups. The emphasis is on understanding the basis of perception, thought, opinion, attitudes, general motivation and learning in individuals and how these vary in human societies and groups. In other words, it deals with the effect of social environment on persons, their attitudes and motivations.

(e) ANTHROPOLOGY

The word 'anthropology' is derived from the root words anthropos meaning man and logos meaning science. It is the study of the physical, social and cultural history of man. The study of human evolution, racial differences, inheritance of bodily traits, growth and decay of the human organism is called physical anthropology. The study of the development and various types of social life is called social anthropology. The study of the total way of life of contemporary primitive man, his ways of thinking, feeling and action is called cultural anthropology (4). Of all the sciences, which study various aspects of man, anthropology is one which comes nearest to being a total study of man. Medical anthropology, deals with the cultural component in the ecology of health and disease.

SOCIOLOGY

Sociology is derived from the Latin socio, meaning society and the Greek logos, meaning science. The word 'society' is derived from the root words socius, meaning individual and societas, meaning group. Society is a group of individuals who have organized themselves and follow a given way of life, and sociology is the study of individuals as well as groups in a society. Sociology can be viewed from two angles: (a) First, it can be seen as the study of relationships between human beings, and how these relationships change or vary in different parts of the world and at different times. The unit of study can be a small group (e.g., family) consisting of parents and children, or the study can extend beyond the family or small groups into the complex society where a greater number of people interact and interdepend in terms of economics, political power, general organization and ways of living. (b) The other part of sociology is concerned with the study of human behaviour. Human behaviour is determined not merely by biological and physical environmental factors but also by social factors. Every form of human behaviour has a social component. Sociologists are interested in the study of the social determinants of human behaviour. In the final analysis it may be stated that the aim of sociology is to search for the pattern of relationships between people in order to pave the way for the betterment of individuals in relation to society (5).

SPECIALIZATION WITHIN SOCIOLOGY

Sociology has grown rapidly since World War II resulting in an increase in specialization within the general field of sociology. Some of the major fields of specialization are: medical sociology, urban sociology, rural sociology, industrial sociology, sociology of religion, sociology of education, criminology, hospital sociology, and demography.

MEDICAL SOCIOLOGY

Medical sociology is a specialization within the field of sociology. Its main interest is in the study of health, health behaviour and medical institutions. As a specialized field, it was first proposed by Charles McIntire in 1894 (6). It is defined as "professional endeavour devoted to social epidemiology, the study of cultural factors and social relations in connection with illness, and the social principles in medical organization and treatment" (6).

Broadly speaking medical sociology includes studies of the medical profession, of the relationship of medicine to public, and of the social factors in the etiology, prevalence, incidence and interpretation of disease.

CONCEPTS IN SOCIOLOGY

Such terms as society, social structure, social institutions, role, socialization, social control mechanisms, customs, culture, acculturation, social problems, social pathology and social survey are frequently used by all sociologists and form part of the necessary equipment by means of which they organize their thinking, do research and communicate the results of research (7). Some of these concepts have also crept into medical terminology and are being increasingly used in epidemiological studies. A brief account of these concepts is given below.

SOCIETY

Human beings everywhere are members of a group or groups. A man who can live without society, said Aristotle, is either a beast or God. A group of people may or may not form a society. For example, a group of people coming together
temporarily for a while to witness a hockey match do not constitute a society; they are merely a crowd. But if the same group of people settle down and organize themselves, then they form a society. Thus, society may be defined in simple terms as an organization of member agents. The outstanding feature of society is a system — a system of social relationships between individuals. The importance of society lies in the fact that it controls and regulates the behaviour of the individual both by law and customs. It can exert pressure on the individual to conform to its norms. In short, society is a vast network of relationships and compulsions that propel, direct and constrain man’s individual efforts. The character of society is dynamic; it changes over time and place. Public health is an integral part of the social system. It is influenced by society, and society by public health. In many places it is the social organization that has made it possible to translate into practice the scientific concepts and achievements. As a result, the mortality rates have been brought to low levels and the life expectancy at birth has soared to very high levels.

COMMUNITY

Various definitions of community are given in dictionaries and other publications. Some imply homogeneity, e.g., “The people living in a particular place or region and usually linked by common interests” (8); or “A group of individuals and families living together in a defined geographic area, usually comprising a village, town or city” (8).

The definition accepted by WHO Expert Committee is — “A community is a social group determined by geographical boundaries and/or common values and interests”. Its members know and interact with each other. It functions within a particular social structure and exhibits and creates certain norms, values, and social institutions. The individual belongs to the broader society through his family and community (8).

SOCIAL STRUCTURE

Social structure refers to the pattern of inter-relations between persons. Every society has a social structure — a complex of major institutions, groups, power structure and status hierarchy. The study of social structure is comparable to the study of anatomy and that of social organization to that of physiology.

SOCIAL INSTITUTIONS

A social institution is an organized complex pattern of behaviour in which a number of persons participate in order to further group interest. The family, the school, the church, the club, the hospital, political parties, professional associations and the panchayats are all social institutions. Within each institution, the rights and duties of the members are defined.

ROLE

In a society, individuals are allocated roles as people in a drama. Sociologists have classified roles into ascribed and achieved, according to whether a particular role is “given” by virtue of sex, age, and birth status or “acquired” by virtue of education or otherwise. In a single day, a man may play a role of husband, father, employee, friend, son, brother, committee chairman, guest, neighbour. The playing of these roles enables him to cooperate with others in many situations according to well-defined roles (9). When a person falls ill, he assumes what is known as a “Sick role”. In this role he is expected to decrease or relinquish his normal duties, seek medical aid, and carry out the orders given by the physician.

SOCIALISM

Socialism, to put it briefly, is the general term for any economic doctrine that favours the use of property and resources of the country for the public welfare. It is a system of production and distribution based on social ownership for raising the living standard of the working class, as opposed to capitalism which is based on private ownership of the means of production and aims at maximum private profit at the expense of the working masses. While the motto of capitalism is ‘all for one’ and ‘each for one’, that of socialism is ‘all for all’ and ‘each for all’. These are two extremes. Ever since Louis Blanc set forth the socialist principle “from each according to his abilities, to each according to his needs”, socialism has undergone many changes and taken varied shades.

SOCIAL CONTROL MECHANISMS

In every society there are rules, formal and informal, for the maintenance of relationships of authority and subordination. The laws and enactments of Parliament are social control mechanisms. In the field of health, there are various Acts, some central and others state or local which help to maintain the standards of health. Even in small organizations, there are sets of formal rules and regulations which control the behaviour of individuals to perform different roles. Besides formal rules, sometimes, informal social pressures are brought to bear upon individuals to help construct “norms” of behaviour. The informal social pressure may be exerted by powerful groups, individuals or friends. These mechanisms work largely through reward and punishment. For example, in India, the government is offering a small financial reward to those who undergo sterilization operation. It is a sort of informal social pressure to further the programme of family planning in India. The social control mechanisms vary from group to group. A study of these mechanisms may be helpful to the community health worker in carrying out the health programmes.

CUSTOMS

The mere existence of a society, the mere plurality of individuals gives rise to customs from which no single member of the community can escape. The ‘highly developed’ societies of the modern world are just as replete with social customs as the ‘primitive societies’ of the past. These customs are quite numerous and quite as powerful. Customs are technically divided into “folkways” and ‘mores’. The folkways are the right ways of doing things in what is regarded as the less vital areas of human conduct. The more stringent customs are called “mores”. The public takes an active part in their enforcement. Laws are generally customs-inspired. The starting point of all customs is
convention. Convention is the practice promoted by convenience of the society or the individual.

CULTURE

The word “culture” is widely used in sociology. It is the central concept around which cultural anthropology has grown. Culture is defined as “learned behaviour which has been socially acquired”. Culture is the product of human societies, and man is largely a product of his cultural environment. Culture is transmitted from one generation to another through learning processes, formal and informal. Culture plays an important role in human societies. It lays down norms of behaviour and provides mechanisms which secure for an individual his personal and social survival. In general, it is widely held, that culture stands for the customs, beliefs, laws, religion and moral precepts, arts and other capabilities and skills acquired by man as a member of the society.

Cultural factors in health and disease have engaged the attention of medical scientists and sociologists. Every culture has its own customs, some of which have a profound influence on the incidence of disease. In developed countries, for example, cancer of the lung from smoking and cirrhosis of liver from drinking are the result of the abuse of widely proclaimed social habits. In India, chewing pan is associated with oral cancer. It is now fairly established that cultural factors are deeply involved in matters of personal hygiene, nutrition, immunization, seeking early medical care, family planning, child rearing, disposal of refuse and excreta, outlook on health and disease – in short, the whole way of life.

ACCULTURATION

Acculturation means “culture contact.” When there is contact between two people with different types of culture, there is diffusion of culture both ways. There are various ways by which culture contact takes place: (1) trade and commerce; (2) industrialization; (3) propagation of religion; (4) education; and (5) conquest. The British brought their culture into India through conquest. An Indian is said to be the next best Englishman. It is because of culture contact, which has both good and bad aspects. The introduction of scientific medicine is through culture contact. The changes in food habits of people is brought about through culture contact: many orthodox Brahmins in India today eat meat. The widespread use of tobacco all over the world is because of culture contact. The radio, the television, the cinema have been important factors in shaping the cultural-behaviour patterns of people.

STANDARD OF LIVING

The term “standard of living” refers to the usual scale of our expenditure, the goods we consume and the services we enjoy. It includes food, dress, house, amusements and in short the mode of living.

The standard of living in a country depends upon: (1) the level of national income; (2) the total amount of goods and services a country is able to produce; (3) the size of the population; (4) the level of education; (5) general price level; and (6) the distribution of national income.

There are vast inequalities in the standard of living of the people in different countries of the world. The extent of differences in the level of living can be known through the comparison of per capita income on which the standard of living of people primarily depends.

DYNAMICS OF SOCIAL CHANGE

The interaction between social factors and health issues is complex and sometimes unpredictable. For example, in Western Europe during the nineteenth century, increase in income and wealth, resulting from the Industrial Revolution, was accompanied by decrease in both birth and death rates. Many authors have in fact argued that increased income was the main cause of these changes (2). The situation in the developing world has varied and differs from the so-called “demographic transition” in Europe. In many parts of Asia, and to a certain extent in Latin America, death rates, particularly among infants, have declined steadily in the past decade and birth rates have declined rather dramatically. Yet the increase in income has been very modest. In Africa, on the whole, death rates, particularly of infants, remain high, birth rates are not declining, the benefits of increased income are not yet apparent, and concern over population growth is just emerging. The relationship between wealth, birth, and death rates observed in the development of West European countries, is thus obviously not universal (2).

A typical feature of traditional societies is a sense of continuity and immutability in patterns of social life. Transitional societies may be better able to cope with change, and modern societies are perhaps best adapted to assimilate rapid changes. A major difference between traditional and modern societies is that, in the former, young people can be fairly sure that their lives will be substantially similar to their parent’s, while, in the latter, young people can be fairly sure that their lives will be substantially different from their parent’s, and that their children’s lives will be different from their own. In transitional societies, young people may simultaneously be involved in two cultures: the traditional one in which their parents grew up and which they still value, and the modern one which may be portrayed in the mass media. A similar clash of cultures may occur in the lives of young people whose families have migrated to another country or from a rural to an urban area (2).

SOCIAL STRESS

A major source of stress, particularly in transitional societies, is the conflict generated by new opportunities and frustrations arising from societal changes. These stress-inducing conditions include: the wave of migration from rural to urban areas and the consequent diminution in the traditional family support system; a greater exposure through mass media to ideas that had been previously culturally alien; tourism; changes in the technological needs of society requiring skills that are different from those of the previous generation and for which the training or education available may be inadequate and the encouragement by commercial interests of economic aspirations that are often unrealistic (2). The pressure is mostly felt where young people have little control over their own destinies, where rapid population expansion means greater competition in the younger age groups, and where resources are inadequate to meet their needs.

It is well understood that the causation of physical and psychological disorders is multifactorial. The experience of stress, particularly in the absence of a social support system or when there is a discrepancy between the actual and perceived demands of a stressful situation, may contribute to further disorders (2). Psychological stress and inadequate coping ability has been implicated as a contributory factor in virtually all diseases (2). In particular, there are direct links between stress and hypertension and coronary heart disease.
SOCIAL PROBLEMS
In a community, there are both individual and social problems. Individual problems become social problems when they affect a large number of people amounting to a threat to the welfare or safety of the whole group. But all individual problems are not social problems. Poverty, crime and disease are the common social problems. Many public health problems are social problems and vice versa. Alcoholism, sexually transmitted diseases, mental illness and narcotic addiction are both, public health and social problems. Such social problems as housing, divorce, population growth, increased number of old people have public health implications calling for a combined sociological and public health action.

SOCIAL PATHOLOGY
The term "social pathology" is given a restricted interpretation linking it to poverty, crime, delinquency and vagrancy. In the modern context, the term is also used to describe the relation between disease and social conditions. The social pathology of accidents, diabetes, cardiovascular disease, cancer, chronic bronchitis have all been subject of recent investigations in medical literature. Social pathology is uncovered by "social surveys".

SOCIAL SURVEYS
Social surveys disclose social pathology. Social surveys have played an important part, in the development of public health. It was such a survey by Chadwick that led to the foundation of the General Board of Health in 1848 in Great Britain. There is a strong kinship between epidemiological survey and social survey. When the objective of the research is to study the role of social factors in the aetiology of disease, the two merge into what is known as "social epidemiology". Large scale social epidemiological studies have investigated the relationship of social factors to heart disease, cancer and arthritis.

CASE STUDY
Case study is a method of exploring and analyzing the life of a social unit - be that unit a person, a family, an institution, culture group, or even an entire community. Its aim is to determine the factors that account for the complex behaviour patterns of the unit and the relationships of the unit to its surrounding milieu. The case study differs from the survey in the respect that it attempts to collect a large amount of information from a small number of units whereas a survey collects a relatively small amount of information from a large number of units. Thus the case study can yield valuable data about the unit studied than is possible from survey data. A combination of survey and case study could, for example, provide more information about a population of interest than either method could do alone. A case study also has its limitations, i.e., a single instance may or may not be representative of a larger population.

FIELD STUDY
Whereas surveys are concerned with the breadth of knowledge (systematic collection of data from population or samples of population through personal interviews or other data-gathering devices), field studies are concerned with depth of knowledge; they involve observation of people in situ.

COMMUNICATION
The term "communication" refers to a social process - the flow of information, the circulation of knowledge and ideas, and the propagation of thoughts. The role of communication in community health is to help motivate people to accept ideas; the ultimate aim of communication is to bring about changes in behaviour. The mass media (e.g., song and drama, radio talks, posters) are extensively used as vehicles of dissemination of information.

SOCIAL DEFENCE
A new concept has come into vogue in recent times - the concept of social defence. It covers the entire gamut of preventive, therapeutic and rehabilitative services for the protection of society from antisocial, criminal or deviant conduct of man. Included in this are measures relating to the prevention and control of juvenile delinquency, eradication of beggary, social and moral hygiene programmes, welfare of prisoners, prison reforms, elimination of prostitution, control of alcoholism, drug addiction, gambling and suicides. Many States in India have enacted the Children Act for the prevention and control of juvenile delinquency. Under the Suppression of Immoral Traffic in Women and Girls Act, services are being provided for the elimination of prostitution in society. Social defence is a system developed to defend society against criminality not merely by treating and defending the offended, but also by creating such conditions in the community which are conducive for a healthy and wholesome growth of human life. The Government of India renamed the Central Bureau of Correctional Services as National Institute of Social Defence in 1975. This Institute is under the Department of Social Welfare.

PSYCHOLOGY
Psychology is defined as "the study of human behaviour - of how people behave and why they behave in just the way they do". It is concerned with the individual, his personality and behaviour. A knowledge of psychology is essential to know others better; to differentiate between the normal and abnormal, to understand attitudes, beliefs, learning and memory processes; and to help promote mental health in individuals and families.

Scope of psychology
Psychology is vast in its scope, as indicated by the numerous branches of psychology, e.g., normal psychology, abnormal psychology, educational psychology, social psychology, child psychology, applied psychology, psychoanalysis, etc. Medical psychology deals with patients suffering from disorders of the mind. Persons trained in medicine and psychology are called psychiatrists. Thus psychology includes every aspect of human life and every type of human relation.

DYNAMICS OF BEHAVIOUR
The theme common to community medicine and psychology is human behaviour i.e., manner of acting or of conducting one self. The main concern of psychology is to study human behaviour. Human behaviour is the result of physical and mental factors (body and mind) interacting in complicated ways. Behaviour is "the total reactions of an individual) accessible to external observation. Thought and understanding are implicit behaviour which are observable not directly, but solely by inference from other observable behaviours."

The broad categories of factors that may influence individual and community health behaviour include:
knowledge, beliefs, values, attitudes, skills, finance, materials, time, and the influence of family members, friends, co-workers, opinion leaders, and even health workers themselves. Serious consideration must also be given to the community or social context in which a given type of behaviour occurs. Pervasive issues such as norms, male/female roles, ethnic discrimination, poverty, unemployment, and educational opportunities may limit the ability of some of the sections of the community to behave in a healthy manner (13).

Cultural and social factors provide a setting for individuals. However, behavioural decisions may also be made that are other than those predicted on the basis of these factors. Psychological factors relating to public health programmes may be considered under the heading of health, illness and treatment behaviours.

Health behaviour

Health behaviour refers to those activities people undertake to avoid disease and to detect asymptomatic infections through appropriate screening tests. For instance, sexually transmitted diseases can be prevented by avoiding sexual exposure with infectious sexual partners. Other health behaviours that might reduce the risks of infection include the use of condoms, of bactericidal products immediately before and after sexual exposure, and the appropriate use of antimicrobial agents with proper supervision (13). In addition the risks of transmission can be reduced by assisting in the detection of infection in sexual partners before they have further unprotected sexual exposure with other susceptible partners. People with good health habits (e.g., daily brushing of teeth, non-smoking) are less likely to develop sexually transmitted diseases than persons with poor health habits (13).

Illness behaviour

Illness behaviour refers to how people react to symptoms. Generally, people who detect symptoms will wait to see if the symptoms persist or worsen. If the symptoms continue, the affected person may ask a friend or acquaintance for advice, before seeking medical help.

Treatment behaviour

Treatment behaviour refers to those activities used to cure diseases and restore health. It is important for patients to take medication as directed, return for tests for cure, and cooperate in efforts to identify untreated cases. Research has not shown that any particular group or personality type is more compliant than any other.

All forms of behaviour are responses to stimuli. For example, a child sees a dog rushing towards him, and starts running away. The sight of a dog rushing towards him is the stimulus and running away is the response. To understand behaviour, we must find out the cause for stimulus. The goal of psychology is to find relations that exist between stimuli and responses.

RESPONSES

The various responses may be classified as follows:

i) Physical responses: habits, skills;

ii) Organic responses: emotions, feelings, tension; and

iii) Intellectual responses: perceptions, thinking, reasoning.

CAUSES

All behaviour is caused, and the causes are very complex. They include:

i) Environmental stimuli

The environmental stimuli (e.g., sight, smell, touch, etc.) reach the cerebral cortex through nerve impulses. The information received is assembled and evaluated. By another set of impulses, the cerebral cortex “orders” the behaviour of the individual. This is known as conscious behaviour. It is the behaviour determined by the standards or expectations of the society, e.g., professional behaviour of doctors with patients. This accounts for the variation in a person’s behaviour in different situations.

ii) Emotions and feelings

Behaviour is also dependant on our feelings and emotions. These stimuli arise from within the body. When we say a person is blind with rage or paralysed with fear, we mean that he is a victim or captive to his own emotions. Emotions thus affect our behaviour. The seat of primary emotions (e.g., anger, joy, hunger) is the thalamus in the brain. It is under the control of cerebral cortex. When the influence of cerebral cortex is removed, as for example, when an injury to cerebral cortex occurs, the person’s behaviour may be affected.

iii) Needs

An individual’s behaviour is also influenced by his needs. The terms – needs, wants, desires and urges are used synonymously.

iv) Motivation

Motivation is an inner force which drives an individual to a certain action. It also determines human behaviour. Without motivation, behavioural changes cannot take place.

v) Intellectual perception

A person’s intellectual perception, thinking and reasoning can influence his behaviour in a given situation. That is why each individual behaves in ways which make sense to him.

Making adjustments

Behaviour is also described as an adjustment to meet the needs of a given situation. For example, when a person does not succeed in something there are several ways he or she can react:

- losing temper and complaining to everyone;
- isolating oneself or simply avoiding facing others;
- making excuses for the failure; and
- accepting failure with good grace and making amends by changing his behaviour or otherwise.

This adjustment is both active and passive. That is why some people blow hot and cold to suit their physical and social environment.

Unconscious behaviour

There is also behaviour of which the individual is not conscious. For example, if ten people witness an accident, we get ten conflicting reports of the accident. This is because of certain forces (e.g., perceptions, prejudices, and notions) which colour the incident, over which the individual has no
control. Another example is that some people forget important things because they are unpleasant and remain happily unconscious about them.

**EMOTIONS**

An emotion is a strong feeling of the whole organism. Emotions motivate human behaviour. An emotional experience is characterized by both external and internal changes in the human being. The “external” changes are those which are apparent and easily seen by others such as changes in facial expression, changes in posture. By studying the facial expression we can find out if a person is angry, happy, depressed or elevated. The “internal” changes brought about by emotions are psychological such as rapid pulse, respiration, increased blood pressure, tension and pain. Usually these changes are temporary, and subside when the individual returns to the “normal”.

Some of the major emotions are:

- Fear
- Jealousy
- Sympathy
- Anger
- Moodiness
- Pity
- Love
- Joy
- Lust
- Hate
- Sorrow
- Grief

Scientists have proved that emotions can be a major barrier to communication. Man is indeed a slave to his emotions. The doctor should be able to understand the emotions of the patient. Once the emotional barriers are broken down, a mutual trust between the patient and the doctor develops, and the patient will begin to talk more freely about himself. This is the basis of doctor-patient relationship. The desirable qualities in a doctor are cheerfulness and an even temperament. Moodiness, emotional instability and getting easily upset are undesirable qualities.

**Some specific emotions**

(1) **FEAR**: Fear is the most common emotion of man. It may produce excitement or depression; flight or flight. Some of the common fears of man are – fear of the dark, fear of dogs, fear of snakes, fear of ghosts, fear of sickness, fear of death, etc. When the fear becomes exaggerated or unnecessary, it is called phobia. Such fears are common in patients with mental disorders; (2) **ANGER**: Anger or rage is another basic emotion of man. It is a reaction of the offensive type. Anger is a destructive force. If it is not controlled, it may impel a person even to commit murder; (3) **ANXIETY**: Anxiety may manifest in such symptoms as rapid pulse and breathing, flushing, tremors, sweating, dry mouth, nausea, diarrhoea, raised blood pressure, etc. Patients admitted to hospitals are anxious. Anxiety leads to tension, and tension to pain. The doctor must understand the patient’s anxiety and give him reassurance. A kind word from the doctor or nurse works like a magic and gives the patient considerable relief from mental anxiety; and (4) **LOVE**: Love is a feeling of attachment to some person. It is a basic emotion of man.

**Role of emotions in health and disease**

Emotional states determine human behaviour. Anger can cause a person to be rude and sarcastic. Disorders of emotion interfere with human efficiency – lack of concentration, lack of appetite, increased risk of accidents, lack of sleep, palpitation, etc. Emotional disorders in children may appear in the form of temper tantrums, abdominal pain, spasms, tics, and anti-social behaviour such as aggressiveness.

**Psychosocial illness**: There are a group of diseases known as “psychosocial diseases” (mind acting on body), e.g., essential hypertension, peptic ulcer, asthma, ulcerative colitis which are attributed to disturbed emotional states.

**Control of emotions**

A well-adjusted and mentally healthy person is one who is able to keep his emotions under control. One should not be carried away by one’s emotions. Children should be shown love and appreciation so that they may grow into emotional maturity. For adults, a happy family life is basic for emotional adjustment. Patients who are anxious need reassurance and their fears must be allayed. The following tips may be useful in controlling one’s emotions: (i) cultivate hobbies, good habits of reading and recreation; (ii) adopt a philosophy of life to enable you to avoid mental conflicts; (iii) try to understand your own limitations; and (iv) develop a sense of humour. A study of psychology helps us to understand the basis of emotions and the need to keep emotions under control.

**MOTIVATION**

Motivation is a key word in psychology. It is an inner force which drives an individual to a certain action. It also determines human behaviour. Motivation may be positive (the carrot) or negative (the stick). Without motivation, behavioural changes cannot be expected to take place. Positive motivation is often more successful than negative motivation. Motivation is not manipulation. A motivated person acts willingly and knowingly. The terms motives, needs, wants, desires and urges are all used synonymously; these terms are interrelated and interdependent.

**Kinds of needs and urges**

It is difficult to define human needs. There are many kinds of needs and urges: (a) **Biologic needs**: These are survival needs. A hungry man needs food, a thirsty man water, a sick man medicine. There are other needs such as sleep, rest, recreation and fresh air. The doctor should be aware of these needs in the day-to-day care of the patients; (b) **Social needs**: The need for company, the need for love and affection, the need for recognition, the need for education are all social needs. Some of these needs are met by the family, and some by the community; (c) **Economic needs**: Economic security, that is security from want, is one which everyone desires; and (d) **Ego-integrative needs**: The desire for prestige, power and self-respect come in this category.

Motivation is contagious; it spreads from one motivated person to another. We make use of motives and incentives in community health work. Motivation of eligible couples for a small family norm is an important activity in the National Family Welfare Programme. Motivation is required to enlist people’s participation in community health work.

**INCENTIVES**

Incentives are among the factors that stimulate motivation and encourage specific behaviours. Incentives can be either intrinsic or extrinsic, material or psychological, self determined or selected by others. An intrinsic incentive is the benefit that comes from solving one’s own problems. Extrinsic incentives are rewards that do not relate directly to the goal towards which the desired behaviour is aimed, for example, financial compensation of individuals undergoing sterilization operation for family planning. Material
incentives are tangible goods or services; psychological incentives include the satisfaction, self-esteem, or enhanced capabilities gained through a proposed course of action (13).

**LEGISLATION**

Legislation can serve as an important tool to support, promote and sustain activities at the community level. Laws should satisfy requirements and, at the same time be compatible with the political, cultural, social, and economic situation of the country. This is essential because laws may antagonize the population and make the community uncooperative.

**OBSERVATION**

Treatment involves lot of correct observation of the patient's condition. Observation involves two mental activities – perception and attention. Hippocrates, the Father of Medicine, laid the foundation of modern medicine by accurate observation of signs and symptoms. By observing an apple fall, Newton formulated the theory of gravitation. By observation penicillin was discovered. Observation is a psychological skill. It consists of the noting of the phenomena of life as they occur. It requires correct use of the senses of seeing, hearing, touch, smell, movements etc. A doctor should cultivate the habit of correct observation. Correct observation leads to correct thinking, reasoning and learning.

Observation promotes attention. To observe more carefully is called attention. A moving object attracts more attention than a static object, a large object attracts more attention than a small object, an uncommon object attracts more attention than a common one, a bright colour attracts more attention than a dull colour. In attention, certain adjustments of sense organs are involved such as turning the head, converging the eyes. In other words, attention means closer observation. Attention is not a fixed state or power of the mind. We constantly change our attention from one object to another according to the demands of the situation. Concentration, i.e., the focusing of consciousness on a particular object to the exclusion of all other objects has been defined as sustained attention.

**Errors in perception**

The word perception implies observation, recognition and discrimination. Perception takes place with the help of sensory organs. Thus we have visual perception, auditory perception, olfactory perception, and muscular perception. The disorders of perception are: (1) Imperception: That is, inability to recognize. This may be due to damage to the sense organs, e.g., anaesthesia; (2) Illusion: An illusion is a false perception. Mistaking a rope for a snake, a tree for an animal are called illusions. Illusions occur in mental diseases. Illusions may be auditory or visual; and (3) Hallucination: Hallucination is an imaginary perception. It is a gross error of perception. Seeing objects that do not exist, hearing sounds that are false, seeing objects moving in a room are called hallucinations. Hallucinations occur in mental disorders.

**ATTITUDES**

Attitudes are acquired characteristics of an individual. They are more or less permanent ways of behaving. An attitude includes three components: (a) a cognitive or knowledge element; (b) an affective or feeling element; and (c) a tendency to action. An attitude has been defined as a relatively enduring organization of beliefs around an object, subject or concept which pre-disposes one to respond in some preferential manner.

Attitudes are not learnt from textbooks, they are acquired by social interaction, e.g., attitude towards persons, things, situations and issues (e.g., government policies, programmes and administrative measures). It has been truly said that attitudes are caught, and not taught. Once formed, attitudes are difficult to change. The responsibility to develop healthy attitudes devolves upon parents, teachers, religious leaders and elders. Our success or failure in life depends upon our attitudes. Social psychology is largely a study of attitudes. In recent years, attitude surveys and attitude measurements have been widely used by psychologists and health professionals.

**OPINIONS AND BELIEFS**

Opinions are views held by people on a point of dispute. They are based on evidence available at the time. Opinions by definition are temporary, provisional. They can be looked on as beliefs for the time being. Beliefs, on the other hand are permanent, stable, almost unchanging. These are usually derived from our parents, grand-parents, and other people we respect. We accept beliefs without trying to prove that they are true. Every community has its own beliefs. As beliefs are held strongly, they are often difficult to change. They can be harmful, helpful or neutral. It is thus easier to give up one's opinions when faced with the facts; attitudes and beliefs do not succumb so easily.

**INTERESTS**

Numerous interests come into play in a communication situation. Most significant are our own interests – of security, pleasure, and self-esteem. Then come the interests of the various groups we are associated with: primary and secondary, as well as the reference groups whose values and norms we aspire to promote. Our communities, castes, language groups, peer groups, and other religious, social, political and professional groups so dear to us are vital to our interests. One must not overlook the social, regional and national interests that shape our selection of communications, and also the way we perceive them (14).

**LEARNING**

Learning is any relative permanent change in behaviour that occurs as a result of practice or experience. It means acquiring something new – new knowledge, new techniques, new skills, new fears and new experiences.

Learning is necessary for man's survival and for human progress. It includes not only acquiring knowledge but also skills and formation of habits, and development of perception. Learning depends largely upon intelligence. Learning also depends upon motivation, and motivation depends on the need students feel to learn. Learning is a continuous process. It is both conscious and unconscious.

**Conditions affecting learning**

(1) Intelligence: Learning depends upon the intelligence or mental faculty of an individual. It involves the activity of sensory adjustment and motor mechanisms of the body. The mental faculty is related to heredity, nutrition and IQ. Children with low IQ are poor learners; they may not learn at all. (2) Age: The curve of learning reaches its peak between 22 and 25 years of age. After the age of 30, there is a sharp decline. It has been appropriately said: You cannot teach
"an old dog a new trick". (3) Learning situation: Physical facilities for learning, viz., institutions, teachers, textbooks, audio-visual aids promote learning. (4) Motivation: In order to learn effectively, there must be adequate motivation. The powerful motives are encouragement, praise, reward and success. These stimulate learning. (5) Physical health: A physically handicapped person, e.g., deaf, dumb, chronically sick cannot learn. (6) Mental health: Worry, anxieties, and fears interfere with learning.

Types of learning
There are 3 types of learning:
(1) Cognitive learning (knowledge);
(2) Affective learning (attitudes); and
(3) Psychomotor learning (skills).

Psychologists have experimented a good deal with animals and man to find out how learning takes place. They have proposed a number of theories: (1) Learning by conditioned reflex: It is well known that when dogs see food, they begin to salivate: this is an inborn reflex. Pavlov, the Russian physiologist discovered that if a bell was rung when the dogs were fed, eventually, salivation could be induced by the ringing of the bell alone. This is called conditioned reflex. The psychologists proposed that learning takes place partly by the mechanism. (2) Trial and error: The lower animals such as apes and cats learn by trial and error method. We also learn a good deal by this method. A child tries and tries again using a number of approaches until accidentally the ideal approaches, becomes obvious. This method of learning is very slow, laborious and primitive. (3) Learning by observation and imitation: We learn a good deal by observation and imitation. A child copies or imitates gestures, facial expressions and movements such as walking. He learns language by observation and imitation. Observation is an important element in medical examination. Observation promotes attention, discrimination and recognition. It was by observation, Hippocrates, Father of Medicine, separated medicine from magic. Part of the doctor's and nurse's education has always been to observe the patient's condition, and to make decisions based on these observations. (4) Learning by doing: In this type of learning there is coordination of muscular responses with sensory impulses. Nursing skills (e.g., bed making, applying bandages, giving bath) are learnt by doing. Learning to type-write or learning a new game or a musical instrument are all examples of learning by doing. (5) Learning by remembering: We also learn by memorizing — remembering dates, events, memorising a poem, remembering faces, etc. (6) Learning by insight: When we are faced with a problem, we solve it by insight or mental exploration. When the doctor makes a diagnosis, some amount of insight is involved. It appears that human beings learn by a combination of methods. (7) Demonstration: Here a procedure is carried out step by step, slowly and accurately before an audience, the demonstrator ascertaining that the audience understands how to perform it. The demonstration involves the audience in discussion, when possible. (8) Field experience: It involves a series of activities for diagnosing problems, planning procedures to solve them and implementing and evaluating these programmes. It provides opportunities to acquire with number of skills. (9) Problem solving: It is closely related to field experience in that the problems are identified and plans to solve them are made, but if the time is short, the plans may be executed by another group of trainees or by the service staff.

Learning is measured by student's performance. There are many ways of measuring student's learning viz., multiple choice questions, essay writing, project work, practical examination, oral examination, etc. Usually a combination of different methods is used.

HABITS
Habit is an accustomed way of doing things, example in the field of health is washing one's hands before handling food. It is usual way of action or an act performed without thinking. Habits are said to have 3 characteristics: (a) they are acquired through repetition (b) they are automatic, and (c) they can be performed only under similar circumstances. Habits accumulated through generations emerge as customs; and customs in turn create habits. Habits once formed persist and influence human behaviour.

Habit formation
Habits are formed. They are of many kinds, e.g., habits relating to food, sleep, work, smoking, intake of drugs and alcohol, etc. There are both good and bad habits. Good habits promote health; bad habits (e.g., drug dependence) may ruin health. Therefore, cultivation of good habits is desirable. The principles involved in habit formation are:
(1) Habit formation should begin early in childhood, when the child has not yet formed any habits, and is receptive to all influences;
(2) Habits are formed by frequent repetition;
(3) It takes time to form habits; they cannot be formed overnight;
(4) There should be a strong emotional stimulus to form habits (e.g., taking a vow, reward, recognition, etc.); and
(5) Good habits kill bad habits. The best way to break bad habits is to cultivate good habits.

Habits build up human personality. Man should not become a slave to his habits, he should remain a master. It is the job of the psychologist to find out how good habits can be developed, and bad ones eliminated.

FRUSTRATIONS AND CONFLICTS

Frustrations
All people have needs — biological, social, economic, which they try to satisfy. When they are unable to meet their needs and desires, they feel frustrated.

The sources of frustration may be external — e.g., unemployment, failures and defeats, or, internal — e.g., lack of health, lack of intellectual ability, etc.

Sometimes, frustration may arouse the individual to higher and bigger effort to overcome failures. The individual may bypass the frustration conditions by changing his goals in life. Frustration, if it is allowed to continue, may damage one's personality. It may generate feelings of anger, dejection, hostility, withdrawal or even attempts at suicide. That is why some people take to drugs and alcohol to escape frustration.

Conflicts
A conflict is like a tug of war between two or more courses of action or between opposing ideas. The person is required to act one way or the other, often generating painful emotions as for example in choosing a life partner or
a job. He has to weigh the pros and cons of the situation to be able to make a correct decision. It is essential for a person's mental health that conflicts should be resolved as quickly as possible, within a reasonable period of time, before emotional disturbances occur.

DEFENCE MECHANISMS

When an individual is faced with problems, difficulties or failures, he employs certain ways or devices to achieve health, happiness or success. These are called defence mechanisms. Psychologists have identified a number of such defence mechanisms, which include the following:

1. Rationalization

   Instead of accepting failure and correcting himself, the individual tries to make excuses and justifies his behaviour. It is like the proverbial fox declaring that the grapes were sour, when it could not reach them. This is called rationalization. It is a face-saving device.

2. Projection

   Sometimes the individual blames others for his mistakes or failures. It is just like the student saying that he could not score good marks in the examination because, his teacher did not like him.

3. Compensation

   Many people make use of compensation to enhance their self-esteem and prestige. The familiar example is that the student who is not good in his studies may distinguish himself in sports or dramatics, music or other activities.

4. Escape mechanism

   Some individuals adopt what is known as an "escape mechanism" to overcome failure or defeat. Some students pretend illness and do not appear for examinations. This is an escape phenomenon. Then there are others who take to alcohol or drugs trying to solve their problems. This is also an escape phenomenon.

5. Displacement

   An office clerk badly snubbed by his superior takes it out on his wife and children on reaching home. This is like a rebound phenomenon. It is trying to escape from one situation and fixing blame on another situation.

6. Regression

   Some people resort to childhood practices (e.g., weeping when something goes wrong) as a mode of adjustment.

   The above list of "defence mechanisms" serves to illustrate the various modes of adjustments the individual adopts to escape from realities. He is either too keen to hide his faults, or run away from his troubles and problems. A mentally healthy person will not use defence mechanisms for achieving success or happiness.

PERSONALITY

The term "personality" is a key word in psychology. It implies certain physical and mental traits which are characteristic of a given individual; these traits determine to some extent, the individual's behaviour or adjustments to his surroundings. The terms personality and human behaviour are inter-related. Psychology, in its broader concept, implies study of human personality. It is important to bear in mind that the personality of the doctor affects very much the well-being of the patient.

Components of personality

There are at least 4 components of human personality:

1. PHYSICAL: These are the physical traits or features of an individual namely height, weight, colour, facial expression, physical health, etc. To the layman, a good personality means an impressive, symmetrical and healthy body:

2. EMOTIONAL: A person's emotions also go into the make-up of his personality. Emotions are the feelings we have—fear, anger, love, jealousy, guilt, worries. These feelings affect an individual's personality;

3. INTELLIGENCE: Personality also implies intellectual ability. An intelligent person will have a forceful personality. A person with sub-normal intelligence is described as a "dull" person;

4. BEHAVIOUR: Behaviour is a reflection of one's personality. It is partly dependent upon our feelings and partly on the expectations of the society. Behaviour is described in such terms as gentle, kind, affectionate, balanced, submissive and aggressive. When we assess human personality, all these components must be taken into consideration.

Personality traits

A trait is described as tendency to behave in a consistent manner in variable situations. Human personality is a bundle of traits. The basic personality traits are established by the age of 6 years. Some traits, we cultivate (e.g., good manners); some, we may conceal (e.g., kindliness); and some, we modify depending upon the society in which we are placed (e.g., sense of humour). The following are some of the personality traits:

- Cheerfulness
- Good manners
- Sportsmanship
- Honesty
- Kindliness

The personality traits we look for in a doctor are kindness, honesty, patience, tolerance, perseverance, consciousness, thoroughness and initiative. It is possible to cultivate these traits.

The Swiss Psychiatrist, Carl Jung (1875–1961) divided personalities into 2 types—extrovert and introvert. The extrovert is a person who is thought to be dashing, practical, active, showing-off and easily mixes with people. An introvert is a person who is reserved, shy and generally keeps to himself. Most people exhibit characteristics of both.

Development of personality

Human life consists of definite stages of growth, and each stage is marked by distinctive psychology. (1) INFANCY: The first one year of life is called infancy. The infant is hardly a social creature. There is rapid physical and mental growth. The infant is totally dependent on the mother. By the end of first year, the infant is able to stand up for a short while and tries to walk with a little support. He enjoys simple tricks and games. (2) PRE-SCHOOL CHILD: This stage is marked by considerable growth of brain. The child feeds himself, speaks, loves his home, fears dark, loves stories and wants to assume responsibility. He begins to mix with other small children. (3) SCHOOL-AGE: The school-age period ranges from 5 to 15 years. The school going child is active all the time. By the age of 8, the mental powers are fully developed. The brain of the child at the age of 8 years is almost of the same size as an adult. The child begins to
reason. There is a gradual detachment from the family, and greater attachment to his playmates and friends. He begins to form groups. The period of childhood terminates with the onset of puberty, which is about 11 years in the case of girls and 13 in the case of boys. (4) ADOLESCENCE: Adolescence or “teenage” is a turbulent period in one’s life. This is a period of rosy dreams, adventure, love and romance. The teenager strives for independence. He dislikes parental authority. He becomes fully aware of social values and norms. There is rapid physical growth. (5) ADULTS: The person is mature and more balanced. The physical and mental characteristics are fully developed. It is difficult to draw a line when adolescence ceases, and adulthood begins. (6) OLD AGE: It is difficult to say when old age begins. It is a gradual process marked by decline in physical powers and acuity of sense organs. Old age is marked by certain psychological changes such as impaired memory, rigidity of outlook, irritability, bitterness, inner withdrawal and social maladjustment.

Character and will

The concept of personality also involves assumptions about character and will of the person. Will indicates determination and character implies moral worth. Personality and character are not identical; both are different. Man’s character may be good at one time and bad at another time, though his personality remains the same. There is no acceptable definition of character.

THINKING

Man is called a thinking animal. Thinking includes perception, memory, imagination and reasoning. It is an active mental process. Imaginative thinking is a mental process, it involves thinking in the absence of original sensory stimuli. Day-dreaming and thinking about our future plans are examples of imaginative thinking. The highest form of thinking is said to be creative thinking, e.g., an artist painting a picture. Creative thinking is said to be responsible for new inventions, new views of life and new discoveries. The anatomical basis of thinking is cerebral cortex. In fact, the purpose of education is to teach people to think, and not merely to memorize facts and figures.

Problem solving

An aspect of thinking is problem solving. It is regarded as the highest stage in human learning. Some problems in life are relatively simple; there are others which are more difficult and complex calling for thinking and reasoning. REASONING requires intelligence. There are several steps in the reasoning process — collection of information on the subject, the arrangement of data carefully, observation of the implications, drawing conclusions and testing the conclusions. An intelligent person reasons well. Reasoning is not always fool-proof. Fallacies may also occur.

INTELLIGENCE

Intelligence is an important aspect of personality. It has not been satisfactorily defined as yet. The widely accepted definition is that it is the ability to see meaningful relationships between things. It includes perceiving, knowing, reasoning and remembering. Psychologists believe that intelligence results from an interplay between hereditary and environmental factors. Some psychologists emphasize genetic factors as having major significance while others emphasize environmental factors.

There is considerable relationship between a person’s degree of intelligence and range of activities, the level of achievement and the depth of understanding possible to him. As psychologists observed the differences between animals and human beings, and the differences between organisms of the same species, they were impressed by the fact that there are variations in the case and adequacy with which adjustments to new situations occur. It was out of such observations that the concept of intelligence arose.

Mental age

The first tests of intelligence were devised by Binet and Simon (1896). They developed the concept of mental age. That is, a child who could do the five-year tests but who could not go on to the six-year level, was credited with mental age of five years. The concept of mental age indicated the level of intelligence achieved, but it gave no indication of the brightness or dullness of the individual concerned. Terman revised these tests, defining intelligence as the capacity to use abstract ideas for solving problems. Gessel indicated four sectors of intellectual development for consideration: (a) motor ability (b) adaptive behaviour (c) language development and (d) personal-social behaviour.

Intelligence Quotient

This is an improvement over the concept of mental age. It is obtained by dividing the mental age by chronological age, and multiplying by 100.

\[ 	ext{IQ} = \frac{\text{Mental age}}{\text{Chronological age}} \times 100 \]

When the mental age is the same as chronological age, the IQ is 100. The higher the IQ, the more brilliant the child. 80 per cent of people have an IQ of or near 100. On the other hand, say for example, if a child is 10 years of age and his mental age level is that of 5 years, the IQ is 50.

Levels of Intelligence

<table>
<thead>
<tr>
<th>Levels of Intelligence</th>
<th>IQ Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>Idiot</td>

</tbody>
</table>

The current interpretation is that the IQ is the measurement of the quality and potential of intelligence. The higher the IQ the more “brilliant” the child is and is more capable of higher performance at school age.

ADULT INTELLIGENCE

The components of adult intelligence have been analyzed by many specialists. Thurstone (15), for instance, defines them as:

1. space: the ability to perceive objects.
2. number: familiarity with elementary arithmetic.
3. verbal comprehension: the ability to reason from verbal concepts.
4. facility of expression: the ability to employ the appropriate words.
5. memory: the ability to retain words and ideas.
(6) induction: the ability to discover principles.
(7) deduction: the ability to use those principles to solve concrete problems.
(8) flexibility and quickness of thought.

Intelligence tests

Intelligence tests can be classified under the categories of group tests and individual tests. These two kinds of tests have been constructed mostly to meet practical necessities. Naturally, if large numbers of subjects are to be tested, it would be more convenient to test them in large group to save time and trouble. But under particular situations, such as in a guidance clinic, each individual could be tested separately and would need to be tested separately. To suit these different requirements, we now have both group tests and individual tests. In a group test, all the subjects must start at one time and finish at the same time just as in an examination. Here, the time factor is constant. One's intelligence is measured in terms of the amount of work successfully completed within the given time. Individual tests on the other hand need not necessarily depend on a constant time factor. Time tests can also be used for individuals. Strictly speaking, all tests of intelligence are measures of performance. However, the term performance is customarily applied to tests which call for a minimal understanding and use of language. These tests provide a measure of fundamental psychological processes, such as reasoning and seeing relationship, without at the same time depending upon particular cultural or educational opportunities. They enable us to measure the intelligence of individuals: (1) who are too young to have learned a language, (2) who are illiterate through lack of educational opportunity or feeblemindedness, and (3) who speak only a foreign tongue.

As the child grows older, his intelligence undergoes a gradual increase. There is an improvement with age in his versatility of adjustment—in the readiness with which he gathers information and acquires new skills which enable him to adjust to the changing circumstances of his environment. When a normally healthy school child, whose educational opportunities have been average, is tested year after year, his IQ remains fairly constant. Changes in educational opportunities lead to fluctuations in IQ. There are cases on record, too, where the IQ rose considerably after glandular therapy.

The chief values of discovering a child's IQ are that: (1) those of low IQ can be taken aside for special education in line with their capacity to acquire intelligent behaviour; (2) those of very high capacity can be selected for education in keeping with their capacity; (3) intelligence tests as an aid in the determination of the right time to enter school; (4) the use of intelligence test in maintaining the adjustment of a pupil to his work; (5) the selection of applicants for college and professional school; (6) the use of intelligence test in educational guidance; and (7) the use of intelligence test to the therapist (16).

Measurement of disability

There have been many attempts to measure or record in standardized form the aspects of behaviour, psychological functions and social performance. One of the most important is Wing's Comprehensive Handicaps, Behaviour and Skills Schedule (HBS) which has been used in epidemiological studies to assess the total child population in terms of detailed scales of specific abilities and disabilities. Results from these surveys have raised important questions about ethnic differences in disability profiles, individual programme planning, defining new syndromes of disability and the possibilities of new parameters for classification. The HBS is essentially a research tool, but Wing has developed from it a small practical schedule for use in service contexts using what had emerged as the most important aspect of mobility, communication and social interaction. The resulting Disability Assessment Schedule (DAS) is being used in several communities as a source of high quality routine data for total population (17).

SOCIAL PSYCHOLOGY

Social psychology is an important branch of psychology. It is defined as the science of behaviour of the individual in society. That is, it studies the behaviour of the individual in group, crowd, mob, audience and other social situations. It also studies the attitudes of the individuals towards cultural and social values.

Group behaviour

Man is a social being. From birth till death, he is associated with people. He is born in particular culture which is made up of customs, laws, ideals, art, literature, crafts, science, technology and institutions. All these act on the individual and influence his social behaviour. Group behaviour is also known as social behaviour.

Social interaction

(a) Inter-personal relationships: The individual learns many things from his parents, teachers and friends. This is known as person-to-person interaction.

(b) Inter-group relationships: The individual is a member of a group, of a family and of a community. He has to follow the traditions of the group. For example, in many communities in India the person is not permitted to marry outside his caste. This is the result of person-to-group interaction.

The individual, through social interaction and social learning acquires patterns of behaviour prevalent in his society, and is accepted as a member of that community. This process of adaptation is known as socialization. Social interaction converts the biological organism into human, social and moral.

As a result of social interaction, the individual acquires attitudes towards persons, things, situations and issues. Social attitudes are shared by others in the community, e.g., attitude to prohibition, family planning, child marriage, etc. In any democratic society, people's attitudes are a matter of vital importance to the State.

Group morale

Every group has leaders. They are responsible for the solidarity of the group behaviour and the morale of the people in the group.

Groups work together. They have definite programmes and objectives. Often their members think, feel and act together. Many community problems can be solved by group effort. We can approach the group through group discussions. The problem is one of how to make these group activities happy and satisfying experiences for those who participate in them.
SOCIETY

Sociology is the science of society. It deals with the study of relationship between human beings, it also deals directly with the study of human behaviour. Whereas the unit of study of psychology is the individual, the unit of study of sociology is the group. Sociology studies man in the context of society and as a part of it.

Medical sociology is a specialization within the field of sociology. Its main interest is in the study of health, health behaviour and medical institutions. Illness is viewed not only as a medical problem but also as a psychological and social problem. The problems presented by patients are not always purely medical but also psycho-social. Diseases such as tuberculosis, leprosy, sexually transmitted diseases have a big social component in their aetiology. Medical scientists are increasingly turning their attention to the study of social, behavioural and cultural factors of illness. A social approach to disease treatment is also emphasized. The doctor needs to have a fuller appreciation of biological, behavioural and social sciences. A successful doctor must possess a knowledge of the community and the factors which affect the health of the community.

THE INDIVIDUAL

Rights of the Individual

During the 19th Century, the rights of man received some small recognition. In 1946 the subject of human rights again received attention. In 1948, the General Assembly of the United Nations adopted the Universal Declaration of Human Rights. The declaration consists of 30 Articles, and recognizes that all human beings are born free and equal in dignity and rights. The Right to better living conditions, and the Right to Health and Medical Service are vital articles. In 1959, the General Assembly of the United Nations also adopted, “The Declaration of the Rights of the Child”. The Universal Declaration of Human rights speaks of the right to health in the following terms:

Everyone has the right to a standard of living adequate for the health and well-being of himself and of his family, including food, clothing, housing, and medical care and necessary social services, and the right to security in the event of unemployment, sickness, disability, old age or other lack of livelihood in circumstances beyond his control.

The Constitution of the World Health Organization expressed itself as follows:

The enjoyment of the highest attainable standard of health is one of the fundamental rights of every human being without distinction of race, religion, political belief, economic or social condition.

Most countries of the world have accepted the idea of the right to health.

The Constitution of India guarantees 7 broad categories of fundamental rights:

1. the right to equality;
2. the right to freedom of speech and expression;
3. the right against exploitation;
4. the right to freedom of practice and propagation of religion;
5. the right of minorities to conserve their culture;
6. the right to property; and
7. the right to constitutional remedies for the enforcement of fundamental rights.

Responsibility for health

Although health is now recognized as a fundamental right of every human being, it has to be earned by individual effort. It cannot be given by one person to another. The responsibility for health rests not only on the individual but also upon the community or State. There are certain responsibilities which the individual must accept or exercise in order to achieve optimum health. These are responsibilities regarding personal health, e.g., diet, care of teeth, skin, recreation, exercise, cultivation of healthful habits, Immunization, reporting early when falling sick, optimum utilization of available health services, etc.

In all civilized societies, the Government or State assumes responsibility to safeguard or promote the health and welfare of its citizens. Russia was the first country to give its citizens a constitutional right to all health services. There is provision for health in the Constitution of India. The Directive principles of State policy of the Constitution of India states:

The State shall, in particular, direct the policy towards securing –

That the health and strength of workers, men and women and the tender age of children are not abused and that citizens are not forced by economic necessity to enter a vocation unsuited to their age or strength.

That children and youth are protected against exploitation and against moral and material abandonment.

The State shall, within the limits of its economic capacity and development, make effective provision for securing the right to work, to education and to public assistance in case of unemployment, old age, sickness and disablement, and in other cases of undeserved want.

The State shall, make provision for securing just and humane conditions of work and maternity relief.

The State shall regard the raising of the level of nutrition and standard of living of its people and the improvement of public health as among its primary duties.

SOCIAL ORGANIZATION

Society is a group of individuals drawn together by a common bond of nearness and who act together in general for the achievement of certain common goals. The individual needs the group – not necessarily a particular group or always the same group or the same group for all needs. Different groups are needed for different purposes; these groups comprise social organization.

The social groups to which people belong are the family, the kinship and caste, religion, village, town or city and the state. Besides these, there are certain functional groups such as the panchayat, the club and various associations. Cutting across these groups, there are groups based on social status.
1. THE FAMILY

The family is the basic unit in all societies. It is the most powerful example of social cohesion. A detailed discussion of the nature and functions of the family is given in the following pages.

2. RELIGION AND CASTE

The caste system in India is an example of a "closed class", i.e., there is no mobility or shifting from one class to another, and the members remain throughout life within they are born. Each caste is governed by certain rules and sanctions relating to endogamy, food taboos, ritual purity, etc. Each caste group within a village is expected to give certain standardized services to the families of other castes. For example, a carpenter repairs tools, a barber (nai) cuts hair, a potter supplies earthenware vessels. In the towns and cities and industrial areas, the caste system, although existing, is not rigid: there is considerable intercommunication and interpersonal relationships not strictly based on caste hierarchy.

3. TEMPORARY SOCIAL GROUPS

(1) The Band: It is the most elementary community of a few families living together. Here the group has organized itself and follows a pattern of life, e.g., gypsies in India.
(2) The Village: The village is a small collection of people permanently settled down in a locality with their homes and cultural equipment. From time immemorial, the village has constituted a basic unit in India. According to the 2011 census, there were 6,40,867 villages in India. The average population of a village is estimated to be 550. This is the general picture, although there are variations. In Kerala for example, houses are not in clusters. It has been stated that the villages in India are like "little republics having nearly everything they want within themselves; and almost independent of foreign relations; they seem to last where nothing else lasts". The survival of the villages and in fact Indian culture, during periods of foreign dependence, has been due to the continuity of village organization. Castes, religion, rituals, kinship, marriages and economy are some of the important aspects of the Indian villages.
(3) The Towns and Cities: From a sociological point of view, a city or town may be defined as a relatively large, dense and permanent settlement of socially heterogeneous individuals. The community is subdivided into smaller groups on the basis of wealth and social class. Because of their size, primary contact among all its inhabitants is difficult. The 2011 census enumerated 7,935 towns and cities in India. When the population exceeds 100,000 it is called a city; on this basis, there were only 107 cities in India at the time of 1961 census.

4. PERMANENT SPATIAL GROUPS

(1) The Crowd: When a group of people come together temporarily for a short period, motivated by a common interest, curiosity, etc., to witness a football match, it is known as a crowd. The crowd lacks internal organization and leadership. When the interest is over, the crowd disperses.
(2) The Mob: The mob is essentially a crowd, but has a leader who forces the members into action. There may be a symbol in the shape of a flag or slogan. The mob is more emotional than a crowd. Like the crowd, it is unstable and without internal organization. When the purpose of the mob is achieved, the group disperses.
(3) The Herd: This is also a crowd with a leader. Here the members of the group have to follow the orders of the leader without question. For example, the gypsies in India.

5. GOVERNMENT AND POLITICAL ORGANIZATION

Some form of government is detectable even among primitive societies. Government is an association of which law is the institutional activity. There is no society which lacks government. It is the supreme agent authorized to regulate the balanced social life in the interests of the public. To understand the organization of medical services in any country, it is essential to know its social and administrative organization.

The various types of government in different countries of the modern world are as follows:

(1) Democracy: This is government of the people by the people and for the people. India and USA have this form of government.
(2) Autocracy: The ruler is absolute in his power, as in Jordan and Ethiopia.
(3) Monarchy: The head of the State is a monarch as found in UK and Nepal.
(4) Socialistic: The production and wealth are owned and controlled by the State. Examples are China and Poland.
(5) Oligarchy: The country is ruled by a small group, e.g., Thailand, Cambodia, Saudi Arabia.

In Capitalist countries, medical service is given to the population by various agencies in various ways. State medicine, insurance medicine, charity medicine and private medicine exist side by side. Medicine has developed into a trade - a service that is purchased by the patient and sold by the physician under a competitive system. In socialist countries, medicine, like education, is not a trade; it is a public function of society. All health activities are directed and controlled by central bodies. Medical service is free and therefore available to all. It is, in other words, socialized medicine.

THE FAMILY

The family is a primary unit in all societies. It is a group of biologically related individuals living together and eating from a common kitchen. The term family differs from household in that all the members of a household may not be blood relations, e.g., servants. As a biological unit, the family members share a pool of genes; as a social unit, they share a common physical and social environment. As a cultural unit, the family reflects the culture of the wider society of which it forms a part and determines the behaviour and attitudes of its members. The family is also an epidemiological unit, and a unit for providing social services as well as comprehensive medical care. The family therefore has engaged the attention of sociologists, anthropologists, demographers, epidemiologists, medical scientists, and in fact all those who are concerned with family welfare.

The word, family, which is used in popular terms, has made a good deal of confusion among the professionals. It is used in very many different senses. To avoid confusion, social scientists have used the term:

(1) Family of origin or the family into which one is born, and
(2) Family of procreation or the family in which one sets up after marriage.

Family life cycle

Families are not constant; they are ever changing. A normal family cycle is generally conceived as having six phases (Table 1).
Situations to reflect the early death of children and even to leave home. Moreover, "leaving home" is essentially an American and European phenomenon that has little relevance in many developing countries in Africa and Asia. A number of variations and exceptions, then, to the typical life-cycle such as the early death of children or one spouse, divorce, childlessness, etc., need to be taken into account.

Family cycle and stress

Structure

Each family experiences its own dynamics of formation, growth, maturation, and dissolution. Crises confronted may be divided into those that are transitional in the family life cycle (e.g., birth of first child or loss of spouse) or nontransitional (e.g., acts of war, uprooting, mental disorders, etc.). Family sociologists have studied effects of sudden shifts in economic status, migration, uprooting, disasters, physical change or incapacity of a family member, and impact of crises at various stages of the family life-cycle. It has been suggested that stress and health hazards are likely to increase when environmental changes occur at critical developmental periods such as, adolescence, first pregnancy, menopause, and retirement. The ability to cope in given situation depends, in part, on perception of threat, motivation and readiness to respond creatively, available emotional and social supports, and cultural provisions. Compared with other social organizations, the average family has distinct disadvantages. Its age composition is heavily weighted by dependents and is of uncertain sex distribution. No other institution is so exposed to crises and stress yet so potentially capable of resolving frustration and releasing tension (19).

Childhood

As noted by number of observers, the literature on delinquency, psychiatric conditions, mental disorders, and other childhood disorders has produced considerable knowledge on insecurity, and incompetence, and on the damage done by marital discord, prenatal rejection, and institutional rearing. Much less is known about conditions facilitating normal development or why some children with a variety of unfortunate disadvantages still manage to develop a healthy personality, emotional security and social competence. Concern with childhood mental disorders is especially appropriate in developing countries, where children under 15 years of age account for about 40 per cent of the population compared to about 25 per cent in developed countries. Poverty and low socio-economic status appear to be associated with a greater incidence of mental disorder (19).

Adolescence

While the age of puberty and physical maturation does not vary greatly throughout the world, adolescence as a stage of physiological growth is more closely associated with economic development, social and cultural values, and historical traditions. The age at which this development phase occurs may differ between countries within the same geographic region. Few nations really have adequate information on drug abuse, the sequelae of inappropriate sex behaviour, alcoholism, and related difficulties.

Parenthood

In modern society, preparation for parenthood is a complex and changing task. Parental skills do not necessarily come easily and naturally. In part, parents behave the way they do because of their own childhood experiences. Persons reared in unhappy, discordant, or disrupted homes are more likely to marry in their teens, to have out-of-wedlock children and to experience unhappy marriages and difficulties in child rearing (19). Such links between childhood experiences and subsequent parental behaviour are not inevitable. There appears to be considerable capacity for modification of parental behaviour, as shown most frequently in the differential treatment of the second child. The stereotype roles of parenthood are losing their validity amidst cultural changes. There appears to be greater social sensitivity too, for example, parent-child communication when one parent dies, the death of an infant in the family, early childhood intervention, single parent families headed by women, and the relationship of family circumstances to wider social environment.

Ageing

India's population ages 60 and older is projected to increase dramatically from 8 per cent in 2010 to 19 per cent in 2050. By mid-century, this age group is expected to encompass 323 million people, a number greater than the total U.S. population in 2012. This profound shift in the share of older Indians—taking place in the context of changing family relationships and severely limited old-age income support—brings with it a variety of social, economic, and health care policy challenges. The ageing of India's population will lead to increases in the prevalence of chronic conditions such as diabetes and hypertension. By one measure, nearly one-half (45 per cent) of India's disease burden is projected to be borne by older adults in 2030, when the population age groups with high levels of chronic conditions will represent a much greater share of the total population (19A). Similar increase in the population of older persons can be anticipated in other regions of the world.

Types of families

Family units throughout the world are not the same. Industrialization, urbanization, democratization and acculturation have affected the family structure and life. Social scientists have described three main types of families.

I. NUCLEAR FAMILY

The nuclear or elementary family is universal in all human societies. It consists of the married couple and their children while they are still regarded as dependents. They tend to occupy the same dwelling space. In the nuclear family, the

Source: (18)
The absence of grandparents, uncles, aunts and near relatives places a greater burden on the nuclear family in terms of responsibilities for child rearing. The husband-wife relationship is likely to be more intimate in the nuclear family than in the joint family. The term "new families" has come recently into vogue; it is applied to those under 10 years of age and consists of parents and children. The concept is important in view of studies relating to family planning (20).

2. JOINT FAMILY

The joint or extended family is a kind of family grouping which is common in India, Africa, the Far East and the Middle East. It is more common in agricultural areas than in urban areas. The orthodox Hindu family in India is a joint family. As a price for education, urbanization and industrialization, we are losing the joint family system.

The main characteristics of a typical joint family are (21) :
(1) It consists of a number of married couples and their children who live together in the same household. All the men are related by blood and the women of the household are their wives, unmarried girls and widows of the family kinsmen. (2) All the property is held in common. There is a common family purse to which all the family income goes and from which all the expenditures are met. (3) All the authority is vested in the senior male member of the family. He is the most dominant member and controls the internal and external affairs of the family. The senior female member by virtue of her being the wife of the male head shares his power so far as the women of the family are concerned. (4) The familial relations enjoy primacy over marital relations. Early and arranged marriage is advocated to ward off any threat from marital relationship.

The merit of the joint family system is that it is based on the motto, "union is strength". There is a sharing of responsibilities practically in all matters which gives the family a greater economic and social security. It provides economic and social security to the old, the helpless and the unemployed. It pools its income to help the young through school, to pay for a marriage or begin a commercial venture.

It offers many of the services and advantages which an industrial society offers through more impersonal governmental, educational and financial agencies.

3 THREE GENERATION FAMILY

The three generation family is confused with the joint family. It is fairly common in the west. This tends to be a household where there are representatives of three generations. It occurs usually when young couples are unable to find separate housing accommodation and continue to live with their parents and have their own children. Thus, representatives of three generations related to each other by direct descent live together.

Functions of the family

The functions of the family have been stated as follows :
(1) Residence : One of the major social functions of the family is to provide a clean and decent home to its members in the west when a man marries he separates from his parents and sets up his own home. In India, it is the prevalent custom among the Hindus that the married couple should reside in the house of the parent. There are two types of residence — patrilocal and matrilocal. In the case of patrilocal residence, the wife goes to the house of the husband; in the

matrilocal residence, the husband goes to live in the house of the wife. (2) Division of labour : In primitive societies, the roles and functions performed by people in family groups were rather well defined. The male had the sole duty to earn a living and support the family. The female had the total responsibility for the day to day care of children and running of the household. In industrialized and urbanized communities, there is less marked distinction between the functions of men and women. On the other hand, there has been an increasing coming together and sharing of responsibilities by men and women. The young wife in India now-a-days brings to marriage not only a dowry but a professional or semi-professional education and she seeks a professional career. This is another new feature of the modern family. The steady enlargement of the freedom of wives, and even children in the family, is leading towards a "communal family" where all its members play a part in its management. (3) Reproduction and bringing up of children : This is a very important function of a family. The mother takes absolute care of the infant and children up to a certain age. The father provides for education and teaches the child the social traditions and customs. (4) Socialization : The family is a bridge between generations and between father and son. It is the transfer point of civilization. The cultural patterns relating to eating, cleanliness, dress, speech, language, behaviour, and attitudes are all transmitted through the family. (5) Economic functions : The family implies economic partnership for the family and the progeny. The inheritance of the property and the ownership and/or control of certain kinds of property like the farm, shop or dwelling are controlled by the family. Eventually the property is handed down to the children. (6) Social care : The family provides social care by (a) giving status in a society to its members, i.e., use of family names where it occurs. Some have a strong feeling of kinship that they belong to a particular family — it denotes some kind of association with someone distinguished in history in that particular society, (b) protecting its members from insult, defamation, etc., (c) regulating marital activities of its members, (d) regulating to a certain extent political, religious and general social activities, (e) regulating sex relations through incest-taboos.

FAMILY IN HEALTH AND DISEASE

Anyone who is concerned with medical practice or community health activities will come to know that family is ultimately the unit with which one has to deal. The family is a group of biologically related individuals. It is a pretty universal picture in all societies. Family performs many functions. There are certain functions which are relevant to health and health behaviour, and are important from the medical-sociology point of view.

1. CHILD REARING

One of the important functions of the family with which medical and community health workers are concerned, is the physical care of the dependent young in order that they may survive to adulthood and perpetuate the family. The way in which child rearing is undertaken differs enormously from society to society, and from time to time, depending upon factors such as capital resources, level of knowledge, state of technology and system of values. It is important to note that patterns of child care (e.g., feeding, nutrition, hygiene, sleep, clothing, discipline, habit training) are passed on from one generation to another. In many societies, child care is socially determined by tradition. The
ideas people have about nutrition, exercise, sleep and clothing have a large social component which varies from society to society and from time to time. For instance child care is more permissive in the East starting with the “on demand” schedule at mother's breast; in the West, child care is more rigid and confined to a set of rules. When the community health worker seeks to improve the health of the child, he meets several obstacles. These obstacles are the traditional ways which are supported by appeals to religion and other sanctions. For example, the problem of overcrowding is not merely a question of room space, but in many instances a question of sleeping habits, a part of a pattern of social customs which foster better relations between groups. Once again, variations between societies may be complex and difficult to change.

2. SOCIALIZATION

The second responsibility of the family is to socialize the “stream of new-born barbarians.” It refers to the process whereby individuals develop qualities essential for functioning effectively in the society in which they live. It is a latent function. By socialization is meant teaching the young the values of society and transmitting information, culture, beliefs, general codes of conduct, by example and precept, in order to make them fit for membership in the wider society of which the family is a part. Organizations such as schools and religious places perform cultural functions for the introduction of the young into adult society. The young are persuaded, given punishments, rewards for good behaviour—all these vary from time to time. In some societies, the young are given freedom to develop into individuals who are freely able to take initiatives.

3. PERSONALITY FORMATION

This is an even more latent function. It is an area in which sociology comes closest to psychology. The capacity of an individual to withstand stress and strain and the way in which he interacts with other people is to a large extent determined by his early experience in the family, mainly with the father, mother and siblings who provide the earliest and most immediate component of the child's external environment. The family acts as a “placenta” excluding various influences, modifying others that pass through it and contributes some of its own in laying the foundation of physical, mental and social health of the child.

4. CARE OF DEPENDANT ADULTS

(a) Care of the sick and injured: In all forms of society, adults may become dependant either through injury, illness or because of basic biological limitation for performing functions normally expected by adults. The attitude of the society in regard to individuals who need care and attention varies considerably. In some societies, there is a great deal of harshness in respect of those who are sufferers. Such individuals are excluded from the full range of benefits. The kind of illness is also of great importance in determining the attitudes of society where the illness arouses fear (e.g., leprosy). However, the family is charged with the responsibility of care of such individuals. The family is expected to provide the front-line care, particularly the mother. Much depends upon her understanding of illness and the extent she believes herself capable of providing nursing care. Studies have shown that the family does more nursing than the hospital, even in highly developed countries (20).

(b) Care of women during pregnancy and childbirth: From the public health point of view, care of women during periods of recognized dependency, i.e., pregnancy and childbirth is an important function of the family. The attitude of society to pregnancy and child-bearing may have an important bearing on the infant deaths, premature and stillbirths, maternal morbidity and mortality. In many societies today, women are given financial help, maternity leave facilities, and nutritional supplements and decreased responsibilities during pregnancy and puerperium.

(c) Care of the aged and handicapped: An area of increasing importance, particularly in the western societies, is the care of the aged and infirm. The increased number of such people has created new problems in terms of long-term care and specialist facilities. Without the support of the family, no amount of medical care can succeed. In India, the joint family provides for such support.

5. STABILIZATION OF ADULT PERSONALITY

The family is like a “shock absorber” to the stress and strains of life. The stress could be injury, illness, birth, deaths, tension, emotional upsets, worry, anxiety, economic insecurity and the like. In such situations, the family provides an opportunity, both for adults and children, for release of tension so that the individual can attain mental equilibrium and strive to maintain a stable relationship with other people. The stress of modern living has increased the importance of mental illness as a public health problem. Alcoholism and narcotic addiction are also a reflection of this trend. Certain chronic illnesses such as peptic ulcer, colitis, high blood pressure, rheumatism, skin diseases are accepted as “stress diseases” having a prominent emotional element in their development. Thus the family has an important function in the stabilization of the personality of both adults and children, and in meeting their emotional needs.

6. FAMILIAL SUSCEPTIBILITY TO DISEASE

The members of a family share a pool of genes and a common environment and together, these dictate their susceptibility to disease (22). Certain diseases such as haemophilia, colour blindness, diabetes and mental illness are known to run through families. Schizophrenia, psychoneurosis and some forms of mental deficiency are also known to have a familial incidence. The family is often the playground also for such communicable diseases as tuberculosis, common cold, scabies, diphtheria, measles, mumps, rubella, chickenpox, dysentery, diarrhoea, and enteric fever. These diseases are known to spread rapidly in families because of the common environment which the family members share.

It is generally agreed that the incidence of congenital malformation is higher among offsprings of consanguineous marriages as compared with non-consanguineous marriages.

7. BROKEN FAMILY

A broken family is one where the parents have separated, or where death has occurred of one or both the parents. Dr. John Bowlby brought out clearly the concept of “mental deprivation” as one of the most dangerous pathogenic factors in child development (23). Separation of the child from its father (paternal separation) and separation of the child from both of its parents (dual-parental separation) are
important factors in child development. Children who are victims of broken families early in their childhood have been found sometimes to display in later years psychopathic behaviour, immature personality and even retardation of growth, speech and intellect (22). Children from these families may drift away to prostitution, crime and vagrancy.

8. PROBLEM FAMILIES

Problem families are those which lag behind the rest of the community. In these families, the standards of life are generally far below the accepted minimum and parents are unable to meet the physical and emotional needs of their children. The home life is utterly unsatisfactory. The underlying factors in most problem families are usually those of personality and of relationship, backwardness, poverty, illness, mental and emotional instability, character defects and marital disharmony. These families are recognized as problems in social pathology (24). Children who are reared in such an environment are victims of prostitution, crime and vagrancy. Problem families may be found in all social classes but are more common in the lower social classes. The health visitor, the health inspector, the midwife, the social worker, the medical officer of health, all can render useful service in rehabilitating such families in a community.

The family therefore plays an important part both in health and disease — in the prevention and treatment of individual illness, in the care of children and dependent adults, and in the stabilization of the personality of both adults and children. In most societies the family is the fulcrum of health services (25). Medical schools are developing teaching programmes in family medicine, because, as Florence Nightingale had said: “the secret of national health lies in the homes of the people”.

CULTURAL FACTORS IN HEALTH AND DISEASE

All people, whether rural or urban, have their own beliefs and practices concerning health and disease. It is now widely recognized that cultural factors are deeply involved in all the affairs of man, including health and sickness. Not all customs and beliefs are bad. Some are based on centuries of trial and error and have positive values, while others may be useless or positively harmful. Some of these cultural factors, hallowed by centuries of practice, have stood in the way of implementing health programmes. Where a change of behaviour was involved, the resistance of the people was maximum in accepting new programmes. Information about these factors, i.e., customs, cultural mores, habits, beliefs and superstitions is still woefully lacking. A brief account of the cultural factors relating to health and sickness, as observed in India, is given below:

1. Concept of etiology and cure

Broadly, the causes of disease, as understood by the majority of rural people, fall into two groups (a) supernatural and (b) physical.

(a) SUPERNATURAL CAUSES : (1) Wrath of gods and goddesses : There are good many people (even among the educated) who believe that certain diseases are due to the wrath of some god or goddess. Chickenpox is an outstanding example, it is known as Chhoti Mata. Where the disease is considered to be due to the wrath of gods and goddesses, administration of drugs is considered harmful.

Cases are not notified and puja's are made to appease the gods (2) Breach of taboo : Breach of taboos is believed by some people to be responsible for certain diseases. Venereal diseases are believed by some to be due to illicit sexual intercourse with a woman of low caste, or a woman during menstruation. (3) Past sins : Diseases such as leprosy and tuberculosis are believed by some to be due to their past sins. (4) Evil eye : A widely held belief throughout the country is the effect of “evil eyes”. Children are considered to be most susceptible to the effect of evil eyes. In order to ward off the effects of the evil eye, charms and amulets are prescribed and incantations recited by the exorcist. (5) Spirit or ghost intrusion : Some diseases such as hysteria and epilepsy are regarded as due to a spirit or ghost intrusion into the body. The services of an exorcist are sought to drive away the evil spirit or ghost.

(b) PHYSICAL CAUSES : Physical causes are also considered to be responsible for certain diseases. Among these are : (1) The effects of weather : Exposure to heat during summer is responsible for an attack of loo (heat stroke). The folk remedies consist of application of oil and ghee on the soles of feet and administration of mango-phool (prepared by keeping unripe mangoes under hot ashes for a few minutes, and extracting the pulp in cold water) with a pinch of salt. (2) Water : Impure water is associated with disease. (3) Impure blood : Skin diseases, viz. boils and scabies are considered to be due to impure blood. Eating neem leaves and flowers is considered to purify blood.

2. Environmental sanitation

(a) DISPOSAL OF HUMAN EXCRETA : Large percentage of people in rural areas use open fields for defecation. This practice is time-honoured and is considered harmless. The average Indian villager is averse to the idea of latrines, where there are no fields for defecation. He is ignorant that faeces is infectious and pollutes water and soil and promotes fly breeding. Thus the problem of excreta disposal is bound up with numerous beliefs and habits based on ignorance. (b) DISPOSAL OF WASTES : The average villager is not aware that mosquitoes breed in collections of waste water. It is permitted to flow into the streets. The solid waste (refuse) is invariably thrown in front of the houses where it is permitted to accumulate and decompose. Periodically it is removed to the fields and used as manure. The animal dung (cow dung) is allowed to accumulate. It is used sometimes as manure and often times pressed into cakes, sun-dried and used as fuel. (c) WATER SUPPLY : The well occupies a pivotal place in the cultural environment of villages. It is also a common meeting place of men and women of the village, when they go to draw their supply of water. It is a place where people bathe and wash their clothes. It is a place where animals are washed and given a drink. These cultural practices lead to the pollution of well water. Tanks and ponds are used for washing, bathing, ablution and sometimes even as a source of drinking water. Some rivers are considered “holy”. People go on pilgrimage to these rivers to have a dip. They not only have a dip but also drink the raw water which they consider sacred. Samples of ‘holy water’ are bottled and carried over long distances for distribution among friends and relatives. Epidemics of cholera and gastroenteritis have been due to these cultural practices. Step-wells are associated with guineaworm disease. (d) HOUSING : Rural houses are practically the same all over the country. They are usually katcha and
damp, ill-lighted and ill-ventilated. For reasons of security, no windows are provided, and if at all one is provided, it is merely a small hole. Absence of a separate kitchen, latrine, bathroom and drainage are characteristic features of an average rural house. Animal keeping is very common in villages. Infrequently, human beings and animals live under one roof. Houses are generally kept clean inside, regularly white-washed or plastered with mud and cowdung.

3. Food habits

Food habits have deep psychological roots and are associated with love, affection, warmth, self-image and social prestige. The diet of the people is influenced by local conditions (e.g., soil, climate) religious customs and beliefs. Vegetarianism is given a place of honour in Hindu society. Even among vegetarians, the pattern of eating is not the same; some do not take onions and garlic on religious grounds. Foods such as meat, fish, eggs, and jaggery are considered to generate heat in the body; foods such as curd, milk, vegetables and lemon are considered to cool the body. These concepts are encountered by the modern physician when treating disease. Adulteration of milk is a common practice. Although the motive is economic gain, a deep-rooted belief is also responsible for this practice, i.e., if pure milk is boiled, the milk secretion of the donor animal may dry up. Muslims observe fasting during Ramzan and Hindus on several occasions. These fasts are considered important adjuncts to religion. Drinks and drugs are among the food habits of the people. Alcoholic drinks are tabooed by Muslims and high-caste Hindus. Ganja, bhang and charas are frequently consumed by sadhus; these habits are now spreading into the general population, especially the younger generation. Eating and drinking from common utensils is considered as a sign of brotherhood among Muslims. Hindu women often take food left over by their husband. In some societies, men eat first and women last and poorly. Some people do not eat unless they have taken a bath. Thus food is a subject of widespread customs, habits and beliefs, which vary from country to country, and from one region to another.

4. Mother and child health

Mother and child health is surrounded by a wide range of customs and beliefs all over the world. Marriage is universal in Indian society, and the family is incomplete without the birth of a male child. This has obvious implications in the context of the country's population problem and male : female ratio. The various customs in the field of MCH have been classified as good, bad, unimportant and uncertain. (1) Good : Customs such as prolonged breast-feeding, oilbath, massage and exposure to sun are good customs. (2) Bad : These vary from society to society. For example, some foods (e.g., eggs, meat, fish, milk, leafy vegetables) are forbidden during pregnancy in some parts of the country. In rural areas, most deliveries are conducted by the traditional untrained dai or birth attendant whose methods of conducting delivery are far from safe. The villagers have great faith in her. In some parts of the country, the child is not put to the breast during the first 3 days of birth because of the belief that colostrum might be harmful; instead the child is put on water, and sugar solution. Branding of the skin, administration of opium and drastic purgatives are all bad customs. The net result of these customs is high infant mortality and morbidity. (3) Unimportant : There are certain customs which are unimportant, viz, punching the ear and nose, application of oil or a paste of turmeric on the anterior fontanelle. (4) Uncertain : Sometimes, it may be difficult to say whether certain customs are good or bad. The practice of applying kajal or black soot mixed with oil to the eye-lids partly for beautification and partly for warding off the effects of "evil eye". Often-times, this custom has been blamed for transmitting trachoma and other eye infections. A knowledge of the local customs and beliefs is therefore very important for improving the health status of mothers and children. This is part of social paediatrics.

5. Personal hygiene

Indians have an immense sense of personal cleanliness, much of which is closely interwoven with ideas of ritual purification. Rituals are "a set or series of acts, usually involving religion or magic, with the sequence established by tradition." (1) Oral hygiene : Indians are very particular about oral hygiene. Many people in the countryside use twigs of neem tree as a toothbrush; some use ashes; and some charcoal. The educated and those who have come in contact with urban life use toothbrushes. Eating pan leaves smeared with lime with or without tobacco is a common social custom. (2) Bathing : Bathing naked is a taboo. Apart from regular baths of which Indians are very fond, there are baths fixed on special occasions. The women after menstruation must have a purifying bath; after childbirth, there may be two or three ceremonial baths, the time for which is fixed upon the advice of the priest. The practice of an oil bath is a good Indian custom. Womenfolk in the countryside use a paste consisting of gram, mustard oil and turmeric powder and rub it on the body before a bath. Thus, bathing is a ritual in India. (3) Shaving : This is done by the traditional barber (nai) in the countryside. He does not sterilize the instruments used, as he does not have any idea of micro-organisms. (4) Smoking : Smoking hubble-bubble is a social custom in some parts of the country. It can spread tuberculosis. Smoking with the burning end of the cigar in the mouth, which is a common custom among villagers in Andhra Pradesh, is associated with oral cancer. The 1971 Report of the Royal College of Physicians of London (26) on the effects of smoking and health provides useful summary of information on the diseases now known to be associated with smoking – cancer of the lung, chronic bronchitis and emphysema, coronary artery occlusion, angina pectoris, cancers of the mouth, pharynx, larynx, and oesophagus, cancer of the bladder and pulmonary tuberculosis. Among patients with peptic ulcer those who smoke have a higher death rate than those who do not. A mother's smoking during pregnancy may retard the growth of the foetus. (5) Purdah : Muslims and some high caste Hindu women observe purdah. The incidence of tuberculosis is reported to be high amongst those who observe purdah, which also deprives them of the beneficial effect of the sunrays. (6) Sleep : Many people in the villages sleep on the ground for reasons of poverty, and they are exposed to insect bites. (7) Wearing shoes : The transmission of hookworm disease is associated with bare feet. Many villagers in South India do not wear shoes. (8) Circumcision : This is a prevalent custom among Muslims, which has a religious sanction.

6 Sex and marriage

Sexual customs vary among different social, religious and ethnic groups. For certain religious groups menstruation is a
According to the 2011 Census, there were 7,935 towns and cities in India. It has been said that civilization means the relatively large, dense and permanent settlements of people. The important aspects of Indian village society. About 550 or 100 families. The villages are self-sufficient, rural people depend primarily upon agriculture. Caste, occupational class system. People in the upper class enjoy better standards of life. There are further sub-divisions into sub-castes. Each caste is governed by certain rules and regulations relating to food, drink, marriage, social contact and rituals. Caste is a judge exercises authority not only in the courts but in the community also. The characteristics of a community are:

- the community is a contiguous geographic area;
- it is composed of people living together;
- people cooperate to satisfy their basic needs; and
- there are common organizations, e.g., markets, schools, stores, banks, hospitals.

In other words, a community is a network of human relationships. It is a major functioning unit of society. It is the place where our home is located; children are educated; sick people are treated and individual basic needs and desires are met.

**THE COMMUNITY**

"No man is an island". From the time of birth until death, all normal human beings are part of a group, the family or community. The characteristics of a community are:

1. The community is a contiguous geographic area;
2. It is composed of people living together;
3. People cooperate to satisfy their basic needs; and
4. There are common organizations, e.g., markets, schools, stores, banks, hospitals.

In other words, a community is a network of human relationships. It is a major function unit of society. It is the place where our home is located; children are educated; sick people are treated, and individual basic needs and desires are met.

**Structure of society**

1. Caste: Indian society is mostly based on caste system. There are further sub-divisions into sub-castes. Each caste is governed by certain rules and regulations relating to food, drink, marriage, social contact and rituals. Caste is a judge exercises authority not only in the courts but in the community also. The characteristics of a community are:
2. Income: On the basis of income, people have been grouped into classes – upper, middle and lower classes.
3. Occupation: Occupation has also been adopted for classifying people. In India, there is no satisfactory occupational class system.

**Rural societies**

India is a land of villages. There are 6,40,867 villages. Out of every 1,000 population, 690 live in villages (as per 2011 census). The average population of an Indian village is about 550 or 100 families. The villages are self-sufficient units for most of the routine requirements of its people. The rural people depend primarily upon agriculture. Caste, religion, ritual, kinship, marriage, and economy are some of the important aspects of Indian village society.

**Urban societies**

Towns and cities comprise the urban society. They are relatively large, dense and permanent settlements of people. According to the 2011 Census, there were 79,925 towns and cities in India. It has been said that civilization means the city and the city means civilization. The city represents the way of living of man in modern age. The occupational pattern of the urban people is different. They depend less on agriculture. There is an occupational diversity. The social life is impersonal and less intimate. Cities are the melting pots of races, people and cultures. Traditional patterns of belief and behaviour tend to be broken down. New ideas and patterns of behaviour emerge which further spread to villages.

**Social mobility**

Indian society is rigidly based on caste system. There is little social mobility, i.e., people do not change their caste or religion. In other words, Indian society is a "closed-class" system. There are societies known as the "open class societies" where movement of the social ladder is unrestricted, on the basis of achievement or gaining wealth. Open class societies are therefore more progressive, where people according to their ability can go up the social ladder. In closed-class systems, it is difficult to make reforms without meeting resistance of the people.

**SOCIAL CLASS**

People in a community are differentiated by certain characteristics which they bear. These may be personal characteristics such as age, sex, marital status, place of birth and citizenship; economic characteristics such as occupation, type of activity; cultural characteristics such as language, religion and caste; and educational characteristics such as literacy and level of education. In Indian communities, especially in rural areas, caste is an important basis of social differentiation. The caste groups are hierarchical and carry different degrees of social prestige, which is correlated with a host of other socio-cultural factors.

Although defined differently in different societies and by different investigators, social class is closely bound up with economic status, level of education, way of life, attitudes and expectations, and exposure to different types and degree of stress. More important, it seems to have a direct bearing on the external resources and internal mechanisms available to individuals in attempting to deal with health problems.

Social scientists have used occupation widely as a means of determining the level of social standing of an individual in a community, because occupation has an enormous importance in all societies for understanding human behaviour. In urbanized and industrialized communities, where there is a substantial division of labour, occupation is a major determinant of social mobility.

Economic rewards: That is income and wealth which can promote or achieve health easier.

Extent of authority: That is, occupation is an important determinant of authority which the individual has over other people; it spills over into his life itself, his pleasures and other activities, through control of purchasing power. Those who receive higher economic rewards tend to be vested with greater authority. For example, a person who is a judge exercises authority not only in the courts but commands respect from other people. His position enables him to acquire authority.

Extent of obligations: The extent of obligations demanded of individuals by the rest of the community will be determined by the occupation he holds. One who holds a high place occupationally has greater obligations.

Degree of status: Closely allied with
the occupational role is the degree of status and standing of the individual in the community. For example, medical practitioners in India enjoy a higher status in society than others. The occupation itself will give the person status irrespective of personal characters, age, and experience. Therefore, occupation is widely used as a measure of social differentiation. In technically advanced countries, occupation tends to range in a hierarchy – those who have high economic rewards have a higher level of prestige than those who are placed low in the social hierarchy.

### Occupational classification

The International Standard Classification of Occupation 2008 (ISCO–08) (27A)

The international standard classification of occupation 2008 (ISCO–08) provides a system for classifying and aggregating occupational information obtained by means of statistical censuses and surveys, as well as from administrative records. It is a revision of ISCO–88, which it supersedes. ISCO–08 is a four-level hierarchically structured classification that allows all jobs in the world to be classified into 436 unit groups. These groups form the most detailed level of the classification structure and are aggregated into 130 minor groups, 43 sub-major groups and 10 major groups, based on their similarity in terms of the skill level and skill specialization required for the jobs. They are:

1. Managers
2. Professionals
3. Technicians and associate professionals
4. Clerical support workers
5. Service and sales workers
6. Skilled agricultural, forestry and fishery workers
7. Craft and related trade workers
8. Plant and machine operators and assemblers
9. Elementary occupations
10. Armed forces occupations

### Limitations of occupational classification

Occupation is a useful measure of social differentiation, particularly in communities highly industrialized and urbanized. We all tend to compare, for example, different social classes in relation to mortality and morbidity. But, there are certain limitations in using social classification based on occupations alone. These may be stated as follows:

1. **Heterogeneous grouping**: Each social class is a heterogeneous grouping of a wide variety of occupations. There is an assumption that these occupations are related to each other, which in fact, is not so. The people in each social class differ not only occupationally, but also in respect of educational status and family background. We have to recognize that categorization into social classes is merely one of convenience.

2. **Occupational mobility**: People sometimes change their occupations. This occupational mobility can lead to discrepancies in using social classes correctly over a period of time. Social classes themselves are subject to change. Certain occupations are promoted in social hierarchy and some demoted. Such changes in social classification may invalidate their comparative use over time.

3. **Women**: There are differences in classifying women alongside men. Some occupations are exclusively occupied by males and some by females. There is also sometimes ambiguity in the nomenclature of occupations occupied by men and women. If a man describes himself as a secretary, it is a highly paid occupation; if a woman describes herself as a secretary, it is usually a position in an office in a low capacity. Inspecting these limitations, social classification by occupation is an effective tool for examining various kinds of data related to people. Much research in social medicine in recent years has centered round social class and disease prevalence.

### Other measures of social differentiation

There are other measures of social differentiation which may be of greater use or significance than occupation. These are:

1. **Education**: It measures the inculcation of values, knowledge and achievements of the individual. **(2) Income**: Another important way of distinguishing people is by the amount of income or wealth. Here again, there are difficulties because people have great reluctance to talk about their income truthfully. **(3) Purchasing power**: This may be of more important value than occupation in classifying people. **(4) Religion**: This is another important attribute of the individual which may have tremendous bearing on the health of the people. An examination of infant mortality among Christians, Hindus and Muslims in India revealed a low rate for Christians, a high rate for Hindus and highest for Muslims. These differences are attributed to religion which has a bearing on the socio-cultural patterns of living involving age-old habits, customs, and traditions affecting cleanliness, eating, clothing, child care and almost every detail of daily living. **(5) Rural and urban**: There are differences in the health and sickness status of people living in rural and urban areas. Rural and urban people differ in their life-style, opinions and values, which have a bearing on the health and sickness status. To sum up, it may be stated that each of these measures which may be employed for social differentiation have a "snag" too and therefore each must be examined critically and used with discrimination depending upon the subject matter of the enquiry.

### Socio-economic status scale

Socio-economic status has been defined as the position that an individual or family occupies with reference to the prevailing average standards of cultural and material possessions, income, and participation in group activity of the community. The social status may be inherited, but in modern society, it is achieved on the basis of occupation, income, type of housing and neighbourhood, membership of certain associations and organizations, material possessions, etc.

There have been many attempts at developing scales for measuring socio-economic status. Hollingshead in USA employed three variables, viz education, occupation and residential address for measuring socio-economic status. Kuppuswamy (28) – in India prepared a scale based on education, occupation and income which are the three major variables contributing to socio-economic status in urban areas. Similar scales have also been prepared by Pareek and Kalshestra (29) for use in rural and urban areas. Kuppuswamy’s scale is fairly widely known. The modified version of the Kuppuswamy’s socio-economic status scale for the year 2007 is given in Table 2. The income scale has been recalculated using All India Average Consumer Price Index for the industrial workers for the year 2001 as the new base year (30, 31).

Wealth Index (32)

One of the background characteristics used in the National Family Health Survey-III was an index of the economic status of households called the wealth index. The wealth index has been developed and tested in a large number of countries in relation to inequalities in household income, use of health services, and health outcomes. It is an indicator of the level of wealth that is consistent with expenditure and income measures. The economic index was constructed using the following household asset data and housing characteristics: household electrification; type of windows; drinking water source; type of toilet facility; type of flooring; material of exterior walls; type of roofing; cooking fuel; house ownership; number of household members per sleeping room; ownership of a bank or post-office account; and ownership of a mattress, a pressure cooker, a chair, a cot/bed, a table, an electric fan, a radio/transistor, a black and white television, a colour television, a sewing machine, a mobile telephone, any other telephone, a computer, a refrigerator, a watch or clock, a bicycle, a motorcycle or scooter, an animal-drawn cart, a car, a water pump, a threshing machine, and a tractor.

Each household asset is assigned a weight (factor score) generated through principal components analysis, and the resulting asset scores are standardized in relation to a normal distribution with a mean of zero and standard deviation of one. Each household is then assigned a score for each asset, and the scores were summed for each household: individuals are ranked according to the score of the household in which they reside. The sample is then divided into quintiles i.e., five groups with an equal number of individuals in each. In National Family Health Survey-III, one wealth index has been developed for the whole sample and for the country as a whole. Thus, at the national level, 20 per cent of the household population is in each wealth quintile although this is not necessarily true at the state level. Table 3 shows the wealth quintiles in India for National Family Health Survey-IV according to residence as urban and rural areas and in major states (32).

As shown in Table 3, 43.7 per cent of the population in urban areas is in the highest wealth quintile; in contrast only

7.5 per cent of the rural population is in the highest wealth quintile. The distribution of the population across wealth quintiles shows large variations across states, with Chandigarh (78.5 per cent), Punjab (60.7 per cent), Delhi (61.1 per cent) and Goa (54.5 per cent) having over one-half of their populations in the highest quintile and Chhattisgarh, Orissa, Bihar, and Tripura, having less than one-tenth of their populations in the highest quintile. In Jharkhand and Bihar, half of the population falls into the lowest wealth quintile. By contrast, in about half of the states, less than 10 per cent of households are in the lowest wealth quintile.

Social class and health

There are a large number of studies linking social class to incidence of disease. Income, occupation and education which are the major components of most measures of social class are also each generally positively correlated with health status. It adds to the conviction that social class affects health. Individuals in the upper social classes have a longer life expectancy, less mortality and a better health and nutritional status than those in the lower classes. Diseases also have been shown to affect people at various social levels differently. For example, coronary heart disease, hypertension, diabetes all have been shown to have a high incidence in social class I and a gradual decline in incidence in the other social classes. Diseases of skin, eye and ears, diarrhoea and dysentery have also shown a higher incidence in the lower classes, which can be ascribed to the poor state of physical environment in which they live. Social class differences in mental illness have also been reported. Infant mortality, general mortality, maternal mortality are all related to social class. To serve as an illustration (Table 4), the National Family Health Survey-4 (2015-16) conducted in India shows the glaring differences in early childhood mortality rates among the households belonging to various wealth index brackets. Infant mortality rates are high among the lowest wealth index households and is lowest among the highest wealth index households.

Social class differences have also been observed in the family structure, and utilization of medical and health services. Families in the lower classes are bigger in size, women marry early and bear more children. The upper social classes are characterized by small sized families and fewer children. Individuals in the lower social classes have been found to make less use of the hospital facilities, consult the doctors less often and are less likely to utilize preventive health services such as prenatal and postnatal care, general check-ups and immunization services. Social classification therefore provides an important means of studying health and disease phenomena in communities, and has proved an effective tool.

**Factors involved in social class differences in health and disease**

It is the first concern of those in preventive medicine and those who provide medical care service to know why there are differences in mortality and morbidity from particular diseases in certain social classes. Many factors may be involved, the following are some : (1) **Physical environment** : Differences in mortality and morbidity may be due to differences in physical environment, e.g., housing, safe water, access to clean air, etc. People in the upper social hierarchy enjoy better physical facilities than those in the lower rungs of society. (2) **Differences in services provided** : There are differences in the availability of services for different social groups. So far as general practitioners are concerned, some areas are relatively unattended as compared to others. On the whole, it seems the unattended areas are the areas where a substantial proportion of individuals live. (3) **Material resources** : Differences in material resources, e.g., income, wealth and possession of tools which can promote or help achieve better health also intervene in the occurrence of disease or in the maintenance of health status in different social groups. (4) **Genetic endowment** : People in one social class tend to marry in the same social class. The differences in genetic endowment may also influence one’s liability to disease. (5) **Educational status** : The educational level varies in different social classes. The ignorant and the illiterate are likely to have much difficulty in pursuing measures which may conduce to good health. (6) **Attitude to disease** : The attitude of people to health and sickness may vary in different social classes, which may account for differences in distribution of disease in the social classes. There are people who regard that illness is a punishment and there are others who regard that illness is due to natural causes. There are people who diagnose illness themselves and there are others who seek early medical aid. The attitudes of people therefore vary in different social classes. The continued differences which show up in many studies of morbidity and mortality and use of medical services are due to the persistence of substantial differences in social class. There is a great field for exploration of value systems, the significance of illness to families in different classes. The aim of preventive medicine should be to reduce the social class differences in health and disease.

**HOSPITAL SOCIOLOGY**

Hospitals are among the most complex organizations in modern society. There has been in recent years an examination from a sociological point of view of hospitals, of medical personnel and of the utilization of medical services. The modern hospital is a social universe with a multiplicity of goals, profusion of personnel and an extremely fine division of labour. The care of the patient is a master value even for those whose work seldom brings them into direct contact with sick people. The patient is the hospital’s client (33). This complex character of the hospital has fascinated the social scientists as a compelling scene for the study of human behaviour.

**Social structure of a hospital**

A hospital is not a static organization. It is subject to change in structure and function depending upon the changes which occur in the community. The structure and functions of the hospital have changed considerably to what they were 100 years ago. Historically, the hospital was more nearly a place of refuge for the sick and homeless, than a
place for medical treatment. It was a charitable institution where one went to die rather than to be cured (33). In contrast, hospitals today are concerned with active medical treatment, mobilizing all that is latest in medical sciences to produce a cure. In the 19th century, hospitals were occupied by poor and old patients. Hospitals today are occupied by all classes of people. The shift in the type of patients occupying hospitals has led to a new doctor-patient relationship. There is an increasing demand for higher academic qualifications which was not typical of the earlier medical organization of the 19th century. This has led to an increasing complexity of specialization within the medical profession and no doctor today can provide single-handedly all the skills and facilities needed for treatment.

The other functions performed by hospitals are teaching either medical or nursing personnel and research designed to increase medical knowledge in which the patient is of secondary importance. The rural and district hospitals concentrate mainly on patient care. Teaching should take precedence over research in teaching hospitals.

The hospital today is a system of increasing complexity — it is a hotel and a school, a laboratory and a stage set for treatment — employing a large number of medical and paramedical personnel unlike the earlier hospitals in which very few professional groups were involved. At heart the hospital is like a federal system with several departments each enjoying considerable autonomy and discretion in its management of work. The great challenge is one of coordination (33). It requires an administrative machinery to run the hospital smoothly and to avoid conflicts between administrative and professional staff, and between professionals. If a sizable portion of a group is dissatisfied, the system will break down.

The democratic ideal has certainly not yet been achieved in medicine. The structure of the wards, semi-private rooms and private rooms in hospitals is an obvious reflection of class lines. The service of the doctor in his private chamber tends to differ from that given in a public clinic not only in the time spent for case examination but in interpersonal attitudes. The public has come to expect hospitals to give tender, loving care to every patient every day (34).

It is said that each hospital has a “personality” of its own — a tempo of work and an emotional atmosphere peculiar to a given hospital, its traditions, its community of staff and patients. The nature of the staff relationships will influence the staff–patient relationships and consequently the outcome of therapy. It is for this reason there are different atmospheres in different hospitals. Some have a good name, others a bad name.

**Medical profession**

There has been an examination from a sociological point of view of the medical profession. The medical profession, like any other occupational group is distinguished by certain characteristics. There is a professional body which controls the right to practice. The licence to practice is embodied in the legislation, and is given to those who have reached a level of competence that is considered minimum. In India, the Indian Medical Council Act was passed in 1933 to establish uniform standards of medical education in the country. A revision of the Act was made in 1956, which provides, in addition, for the maintenance of the All India Medical Register. The State Medical Councils control the right to practice and certain standards of practice and personal conduct are imposed upon its members. There is great insistence of maintenance of confidentiality and right to practise medicine is withdrawn if there is professional misconduct. In other words, the State is regulating the relationship between professional men and their clients. Some of the possible conflicts in the medical profession may stem from the rules and regulations to which they are bound. The abolition of private practice, by Government doctors is an example of recent conflict.

**Medical care — an Industry?**

The traditional physician was a self-employed small businessmen, with many of the same problems, goals and attitudes as other small businessmen. His practice was “solo-practice” based on “fee-for-service.” Significant changes have taken place in the practice of medicine. The development of new diagnostic and therapeutic techniques require not only large capital investment but also skilled team of personnel. A large number of non-medical personnel are also involved in producing medical care. Society is being increasingly asked to subsidize medical education and medical care. There is a rapid development of insurance and other types of pre-payment. Now it is a national policy in many countries to make the best of known medical care available to all who need it regardless of economic status. Medical profession with its knowledge, experience and dedication is leading the way to developing better systems of health care for all. In economics, an industry is defined simply as a collection of individuals and institutions engaged in the use of similar scarce resources to produce similar goods or services. Sociologically speaking, medical care has the features similar to big industry (35).

**Specialization (36)**

The vast increase of medical knowledge during the 20th century has contributed to specialization in medicine. There are at present no less than 20 recognized specialities and many more sub-specialities. A specialist is defined as one who learns more about less and less. He is concerned with a particular organ or part of the body as opposed to the traditional general practitioner or “family doctor” who is concerned with the “whole person” or even the family.

Specialization has created problems for the traditional doctor–patient relationships. The specialist does not establish close relationship with the patient. As a consultant, he is less likely to maintain a continuing relationship with the patient. It is difficult for him to give the patient the requisite emotional support and understanding that is needed and which is the essence of a good doctor–patient relationship. Besides, specialization has encouraged jurisdictional disputes between one specialty and another and between specialists and generalist.

In short, specialization divides both doctor and patient; places strain on the traditional doctor–patient relationship; contributes to depersonalization. The social role of medicine with the assistance of the humanities and social sciences is forgotten. Over-specialization can lead to a lopsided development of the health services. Sociologists are paying increasing attention to an examination of the medical value system, the forces behind specialization, and selective factors in medical career choices (36).

**Doctor–patient relationship**

An important area of medical sociology is doctor–patient relationship in which complex social factors are implicated. The patient comes unbidden to a doctor and enters...
voluntarily into a contract in which he agrees to follow the doctor's advice. By virtue of his technical superiority, knowledge and skill, the doctor exercises an authoritative role and issues "orders" to his patient. Some individuals may not be prepared to invest the doctor with full authority, this may lead to conflict between the doctor and patient.

Besides technical competence, the doctor must know how to communicate with his patient. In fact, a successful doctor is one who knows how well to communicate with his patient. In this regard, three levels of communication have been described (37): (1) Communication on an emotional plane: The doctor must give a sympathetic ear to the complaints made by the patient and his relatives. This is necessary to establish a quick rapport. The reason why folk medicine is successful is because the patient and his relatives feel they can talk more freely to a folk medical practitioner than with the modern physician. The interpersonal relationships between villagers and folk practitioners on one hand, and the villagers and the practitioners of modern medicine on the other hand are considerably different. (2) Communication on a cultural plane: Secondly, the doctor should be aware of the general concepts of culture and social organization of the community with which he is dealing. This helps to acquire certain "flexibility" in his dealings with patients. The reason why the indigenous and folk systems of medicine are successful in the rural areas is because they are part of the total way of life of the people: treatment is based mostly on charity, and payment to the physician may be in kind, and the medicines are prepared from ordinary plants common to the region. All these are appealing to the common man. Against this background, the western system of medicine is alien to the cultural patterns of the rural folk. To be successful, the modern doctor should couch his scientific advice in terms which fit an already existing cultural pattern. Then there is a great chance that this advice will be followed. For example, in communities where diseases and medicine are classified as "hot" and "cold," it might be helpful for the doctor not to challenge this belief openly. A mere statement to a patient that the medicine is "hot" and will help to cure a "cold" disease may make for increased confidence. Anthropologists have therefore stressed the importance of understanding the community as a whole, its general cultural patterns and its social and political structure, and the native concepts of health and disease. (3) Communication on an intellectual plane: Practitioners of modern medicine come from well-to-do-families. By their education and training, they tend to be sophisticated. This leaves a wide gap between the intellectual level of the practitioners of modern medicine and the illiterate masses. In other words, there is an enormous "social distance" between the two groups. A successful doctor is one who reduces this distance and is able to communicate with his patient freely and wins his confidence. A most important component of doctor-patient communication is humour. It is the best icebreaker for the patient frozen by fear and anxiety.

The doctor who is able to communicate with his patient on these three planes is bound to give maximum psychological satisfaction to his patients. The other qualities which mar the reputation of a doctor are his greed for money, differential treatment between the rich and poor, and lack of a sympathetic and friendly attitude. The patient can challenge the doctor's professional adequacy if the doctor does not know how to communicate. Patients who do not behave according to the doctor's expectations are often labelled as "un-cooperative."

Doctor–nurse relationship (38)

Medicine and nursing have common goals – the preservation and restoration of health. Yet their roles in achieving these objectives are not identical. The primary role of medicine comprises diagnosis and treatment – the "cure" process. In contrast, the primary role of nursing lies in the "care" process – consisting of caring, helping, comforting and guiding.

In the medical–care team, the physician tends to be autocratic and looks upon the nurse primarily as his helper following his orders and carrying out whatever he chooses to delegate. Because of the authoritarian role of the physician, the role of the nurse in guiding, helping and comforting the patient go largely unrealized. This is more so as technology is advancing, the nurse is asked increasingly to take up tasks instrumental to diagnosis and treatment. In effect, many of the patient's psychosocial needs persist, unidentified and unmet.

Currently, leaders in both the professions are exploring new approaches and roles with a view to provide improved patient care (36).

The sick role

To be ill is more than a medical condition. The sick person has to behave in certain prescribed ways. He comes unbidden to a hospital. As he strips off his clothing, so he strips off his customary identity in the world. He becomes subject to a time schedule and a pattern of activity not of his own making. He becomes passive for most part. He may even become child-like (33). Four aspects of the sick role have been described: (1) the sick person is exempted from his normal social responsibilities depending upon the severity of his illness, (2) he needs to be cared for, (3) sick role is regarded as a misfortune, (4) the sick person is obliged to seek competent medical care, and to cooperate with the doctor in the process of getting well. A typical sick role is temporary, but some patients prefer a prolonged sick role in order to escape everyday responsibilities.

Medical social work

Medical social work had its beginning in England in 1895 when a social worker, known as "Almoner" was appointed at the Royal Free Hospital, London. Later on in the United States, the term was expanded into medical social work. Today, medical social work, has grown into an important field of social work, and an integral part of medicine. Medical social work uses "case work" as its main technique to find out the social background of illness; this information helps the doctor in arriving at a social diagnosis, treating illness and estimating the prognosis. The purpose of medical social work is to help sick people - individual by individual, both through the best use of the patient's capabilities and community resources in matters of personal and social adjustments in the community, including rehabilitation. The person who can best do this type of work is one who had special training in social case work, the medical social worker

Medical social worker

The medical social worker is a paramedical worker who has been trained in social case work, and in the art of interviewing people. There are many situations, in medical and public health organisations, where medical social workers are being employed, e.g., hospitals, tuberculosis clinics, family planning clinics, cancer control centres.
From medical ethics to social ethics (39)

Since antiquity, the doctor/patient relationship has been governed by systems of medical ethics drawn from the Hippocratic, Chinese, Indian and other traditions. All held that the patient's good transcended other considerations. The physician determined what was the patient's good. Modern codes have added a social dimension, a responsibility for the health — the good of society and humanity in general, and a concern for justice. “Health for all”, with its emphasis on social justice, on the equitable allocation of resources and on the responsibility of communities and individuals for their own health, is an expression of this change, and thus represents an ethical as well as a social goal.

The transformation of medical ethics has been stimulated partly by the progress of medical biotechnology and partly by profound social changes, associated with a recognition of human rights and freedoms, and of individual autonomy. Many medical choices can no longer be made purely on the basis of medical science. The emphasis on the social good has confronted lay individuals, whether policy-makers or patients, with ethical decisions and choices, requiring them to share with or often replace the physician or the scientist in determining what is ethically acceptable and good, to balance the patient's interests with those of society.

The explosion of expensive medical technologies, often of limited value to the patient, and the rise in people's expectations, have accentuated the problem of making the best use of limited resources. Policy-makers must set priorities to guide the allocation of resources among health goals and between health and other social goals. They do so under many pressures — social, economic, political, technological and ethical. They are forced to make choices often with tragic consequences. In principle medicine can use the full potential of modern biotechnology — for transplanting organs, for assisting reproduction, for postponing death, for reducing hereditary diseases, even for manipulating the genetic makeup of human beings. In practice the policy-maker by controlling resources and trying to reflect the dominant values of society, determines how much medicine can do, and even which patients may benefit. Thus the good of society and individual good may come into conflict.

For their part, individual patients today exercise autonomy and informed consent in deciding whether or not to accept or continue with treatment, even to continue to live, to become a subject of research, to permit the use of personal health data for study purposes, to be told — or not told — the truth, to permit the use of embryos, to donate organs and to withdraw life-support systems.

Individuals, like communities, are often the subjects of research, such as trials of drugs or vaccines or epidemiological studies. Some living in deprivation or even oppression are liable to exploitation. Researchers have a particular ethical responsibility to safeguard the rights of such people and to observe scrupulously the ethical principles of beneficence, avoidance of harm, and justice.

Consumer Protection Act

Consumer rights have become an important issue. For the first time in India, the Consumer Protection Act 1986 provided consumers a forum for speedy redressal of their grievances against medical services. In the entire health care delivery system the most vital sector is the medical profession. The active participation and dedication of doctors is very important for its survival. Over the centuries the medical profession has been accorded respect by the society. Since last decade or so, increasing commercialization of the profession has eroded this faith.

As far as the professional services are concerned, the evolution of law has followed a set course. Under the general law, a member of a profession is required to show a standard of care which a person of that profession is expected to possess. In developed nations such as USA and UK, patients do not encounter many difficulties, as the courts have developed principles of law which give important rights to patients. In India, people were not going to Civil Courts freely because court fee is very heavy and there is long delay to get final verdict. It may take several years. Parliament has provided an alternative, a quick, efficacious and economic remedy. According to this Act, the decision should be taken within 3 to 6 months. There is no court fee payment and the person can plead his own case. More recently even ESI hospitals have been brought within the ambit of the Consumer Protection Act. COPRA is a piece of comprehensive legislation and recognizes six rights of the consumer, namely: right to safety; right to be informed; right to choose; right to be heard; right to seek redressal; and right to consumer education.

If a patient or the relations of a patient feel that the suffering or death of a patient is because of either negligence by the concerned doctor or the health facility, they can complain to the Medical Council of India or to the Consumer Court. The Medical Council of India, which is a statutory body created to monitor the medical profession has only ethical jurisdiction. The council can only cancel the registration of the concerned doctor temporarily or permanently but cannot punish a doctor or give a compensation.

A complaint against the medical professional can be filed in the consumer court. It should contain all the details of the case, an expert certificate or opinion from the doctor of concerned speciality (stating the complaint is prima facie true and needs further investigation) and the compensation demanded. These courts can only give compensation. The monetary limits of the compensation that can be granted by the consumer courts are as follows: (a) District Consumer Court — up to Rs. 20 lacs; (b) State Commission — Rs. 20 lacs to Rs. 1 crore; and (c) National Commission — above Rs. 1 crore.
Rights of the patient

1. Right to information on healthcare services available to them, diagnosis and treatment;
2. Right to have information about professionals involved in the patient care;
3. Right to safety from errors and malpractice;
4. Right to confidentiality and privacy;
5. Right to have prompt treatment in an emergency;
6. Right to get copies of medical records;
7. Right to informed consent;
8. Right to refuse to participate in human experimentations, and research;
9. Right to be informed about the rules and regulations of the hospital that apply to the patient and the facilities obtainable by the patient;
10. Right to choose and to seek second opinion about the disease and treatment etc.; and
11. Right to complain and have compensation within reasonably short time.

THE ART OF INTERVIEWING (40)

Interview is a device for investigation. It is an instrument of research. The chemist carries out research in test tubes; the bacteriologist uses the microscope in his laboratory. In much the same way, the social scientist uses the interview technique in his investigations. Modern medicine has changed its character; it has emerged as a social science in recent years. Social and psychological factors have come to be recognized as dominant factors in the natural history of disease. In order to elicit these factors, it may be necessary to employ the interview technique. It may be said that the interview technique is one of the contributions of social science to modern medicine.

Aims of interview

The major aims of interview are: (1) to secure information through face-to-face association and thereby gain the portrait of the entire personality, broad enough to encompass the social and psychological background (2) to form a hypothesis (3) to collect personal data for quantitative purposes and (4) to collect data from persons who are secondary sources of information.

Kinds of interview

Social scientists have described four kinds of interview: (a) Direct or structured interview: A schedule containing a set of predetermined questions is prepared. The researcher gets answers to these questions only. Generally the researcher does not add anything to what has been stated by the subject. He does not even alter the language. (b) Non-directive or Unstructured interview: No predetermined questions are asked. The researcher collects information by free discussion. The subject is asked to narrate in his own words his experiences, opinions or reactions about the particular subject under investigation. (c) Focused interview: This type of interview is generally used to study the social and psychological effects of mass communication, e.g., reaction of a film show or radio programme. The researcher tries to focus his attention on a particular aspect of the problem and tries to know the experiences, attitude and emotional responses regarding the concrete situation under study. (d) Repetitive interview: It is used when it is desired to note the gradual influence of some social or psychological process. A record has also to be maintained to study the change in continued sequence.

Technique of interview

Conducting an interview is both an art and science. Sociologists have described the following steps for conducting an interview (40).

1. ESTABLISHING CONTACT

The first requisite before conducting an interview is to establish contact with the interviewee. Prior appointment regarding the time and place of interview is always desirable. It gives the interviewee a sense of satisfaction and a feeling of importance that his time has been valued.

2. STARTING AN INTERVIEW

The beginning should always be made from a general discussion of the problem. The researcher should create an atmosphere in which the interviewee freely tells his story in his own way. The researcher should let the interviewee do most of the talking, while he should himself listen to it attentively guiding and directing the interviewee about the subject matter wherever necessary. All controversial matters must be carefully avoided.

3. SECURING RAPPORT

A state of rapport must be established between the interviewee and the researcher. In the beginning every interviewee proceeds very cautiously giving only formal information. He may not like to discuss personal matters with a stranger. It therefore requires tact on the part of the researcher to create a friendly atmosphere and gain the confidence of the interviewee. Once rapport is gained and hesitation and shyness are overcome, the interviewee may feel overzealous to tell everything that he knows, and all that he feels without any attempt at secrecy or formality. The research worker must utilize this situation to the fullest advantage, and use it as best as he can. The state of rapport, sometimes may not last long; once the interviewee has relapsed into his former state, it may be very difficult to bring him back to rapport.

4. RECALL

At times, during the course of an interview, the interviewee may be so full of emotion that he drifts away from the main subject, and may even go into silence at the end of the narration. At such times, the researcher should give enough time to the interviewee to recollect and start again. At times, it may be necessary to refresh his memory by pointing out what he had been saying last.

5. PROBE QUESTIONS

When the interviewee, during an interview knowingly or unknowingly side-tracks some important aspect of the problem, the researcher has to be very cautious in catching these slips. Great care should be taken in putting probe questions. They should appear to the interviewee to be born of mere curiosity. If the interviewee has deliberately side-tracked a particular point, a very shrewd effort is needed to make him discuss a point at length, the same should not be doggedly pursued, lest rapport should be lost.

6. ENCOURAGEMENT

During the course of an interview, it is necessary to encourage the interviewee from time to time, by interpolating such complimentary expressions as “what you have said is really very illuminating; I never had such an
The procedure to be adopted in operational research differs according to the nature of the study. The usual procedure adopted generally consists of the following phases:

1. Formulation of the problem.
2. Collection of relevant data, if necessary, by a suitable sample.
3. Analysis of data and formulation of hypothesis.
4. Deriving solutions from the hypothesis or “model.”
5. Choosing the optimal solution and forecasting results.
6. Testing of solution, e.g., pilot projects.
7. Implementing the solution in the whole system.

**Operational research team**

Operational research is a team work job and involves several workers. The composition of the team varies with the type of research. The minimum composition in social medicine applications is probably a public health administrator, an epidemiologist, a statistician, and a social scientist. This is in addition to ancillary workers such as clerks, peons and field workers. The team is headed by a director who is responsible for the whole project.

**Social problems**

In a community, there are both individual and social problems. When individual problems affect a large number of people, they become social problems. Some of the present day social problems are alcoholism, drug dependence, STD, vagrancy, juvenile delinquency, prostitution etc. Some of the social problems have medical implication, e.g., venereal diseases. Social problems are solved by social and political action, that is by social welfare programmes, social assistance, social legislation in the community to curb the social evils (e.g., The Prevention of Food Adulteration Act; The Prevention of Immoral Traffic Act; The Medical Termination of Pregnancy Act).

**Prostitution**

Prostitution is an age-old social evil. It is a social problem in most urban areas, and to a lesser extent in rural areas. Sociologists who have studied prostitution have mentioned the following underlying causes of prostitution. (1) changes in environment (2) breakdown of family relations (3) parental quarrels (4) want of affection (5) illegitimate love (6) easy money (7) low I.Q. (8) low moral standards (9) poverty, etc. The Government of India passed an Act in 1956 known as "The Suppression of Immoral Traffic Act in women and girls" which bans prostitution in its commercialized form as an
organized means of living. The Act was amended and retitled as "Immoral Traffic (Prevention) Act" in 1986. It covers all persons, whether male or female, who are exploited sexually for commercial purposes.

**Delinquency**

A delinquent is one who shows deviation from normal behaviour. In other words, he is one who has committed an offence, e.g., theft, sexual offence, murder, burglary, etc. Delinquency is a social problem in many communities. The causes responsible for delinquency are social maladjustment, poverty, disturbed home conditions, alcoholism, drug addiction, and modern ways of living.

The programmes for the prevention and control of juvenile delinquency centre round the implementation of The Children Act, 1960 which provides a specialized approach towards the care, protection, maintenance, training and rehabilitation of delinquent children. The institutional infrastructure consists of Juvenile/Children's Courts, child welfare boards, remand homes, certified schools, children homes and after-care facilities.

**Dowry system**

Dowry started as an innocent custom, a symbol of love from parents to their daughter on the eve of her marriage. But it has, in recent years, grown into a social evil with many instances of bride-burning and suicides. These are symptoms of societal corruption.

Under the Dowry Prohibition (Amendment) Act, 1986 the minimum punishment for taking or abetting the taking of dowry has been raised to 5 years imprisonment and a fine of Rs.15,000. What is required is a sustained effort to go into the root causes of these evils. Well-entrenched social customs cannot be easily erased by an Act of Parliament.

**Drug addiction**

Drug addiction is defined as a state of periodic or chronic intoxication detrimental to the individual and society produced by the repeated intake of habit-forming drugs.

Drug abuse has reached an alarming proportion in recent years. "Drug culture" is fast making inroads into the lives of young people from all walks of life. The reasons given for drug dependence include the following:

- curiosity and natural tendency to experiment with drugs.
- disturbed home environment: children from broken homes, indifferent parents, lack of communication between parents and children.
- an escape phenomenon from tensions and frustrations in life, e.g., unemployment, failure in examinations.
- impact of disco culture, mobile, TV, internet etc.
- ignorance regarding the habit-forming nature of the drugs.

To call a person a drug addict, the following criteria must be satisfied:

1. **Psychological dependence**: there is an overpowering desire (compulsion) to take the drug and obtain it by any means.
2. **Physical dependence**: when the drug is withdrawn, the patient shows "withdrawal symptoms" such as irrational and violent behaviour, nausea, diarrhoea, watering of eyes and nose, etc.

(3) **Development of tolerance**: there is a tendency to increase the dose.

**Management**

Though drug addiction may be considered as a social problem, the first step in its management is medical care, which includes:

- identification of drug addicts and their motivation for drug detoxification.
- detoxification (requires hospitalization);
- post-detoxification counselling and follow-up (based on clinic and home visits); and
- rehabilitation.

Simultaneously with medical treatment, changes in environment (home, school, college, social circle) are important. The patient must effect a complete break with his group, otherwise the chances of relapse are 100 per cent. Psychotherapy has a valuable place in the management of the addict.

Preventive measures include education of target groups and the general public through TV, radio, leaflets, and posters to create awareness of the problem. The Government have promulgated an Act called the "Narcotic Drugs and Psychotropic Substances Act" which came into force in 1985 to combat this problem. Refer to Chapter 17 for further details.

**Alcohol abuse**

Alcoholism is world-wide social and medical problem. Over the past 30 to 40 years, alcohol consumption has increased in quantity and frequency. The age at which people start drinking has also declined. The population groups at great risk are those undergoing rapid socio-economic and cultural changes; they view alcohol as a symbol of prestige and social status.

Consequences: The consequences of alcohol abuse cover a wide spectrum: crime, murder, prostitution, neglect of families, malnutrition, disease (e.g., cirrhosis of liver, alcohol-dependant syndrome, alcoholic psychosis), unemployment, indebtedness, child delinquency, road accidents, loss of friends and self-esteem. In short excessive alcohol results in serious medical, psychological and sociological problems.

Drinking by adults serves as a role model for the young. The identification of risk factors is essential for prevention. As drinking patterns vary considerably, the prevention of alcoholism is not easy. A widespread public education and discussion, and investigation of public attitudes may result in measurable improvement. This should be combined with social welfare and health services. Refer to Chapter 17 for further details.

**Unmarried mothers**

We do not have accurate statistics regarding unmarried mothers in India. Because of social customs and traditions in India, the problem of unmarried mothers in India must be insignificant. Such mothers have a multiplicity of needs - not only for medical termination of pregnancy and health risks but for understanding, warmth and guidance. In Western societies, where this problem is acute, they have special schools and counselling programmes for teenage mothers.
Handicapped

The handicapped comprise 7 main categories as shown below, during 2011 (43).

<table>
<thead>
<tr>
<th>Categories</th>
<th>Estimated number in India</th>
</tr>
</thead>
<tbody>
<tr>
<td>(i) The blind</td>
<td>5.03 million</td>
</tr>
<tr>
<td>(ii) The hearing disability</td>
<td>5.07 million</td>
</tr>
<tr>
<td>(iii) The orthopaedically handicapped</td>
<td>5.43 million</td>
</tr>
<tr>
<td>(iv) Multiple disabilities</td>
<td>2.11 million</td>
</tr>
<tr>
<td>(v) The mentally retarded</td>
<td>1.50 million</td>
</tr>
<tr>
<td>(vi) The mental illness</td>
<td>0.72 million</td>
</tr>
<tr>
<td>(vii) The speech disability</td>
<td>1.99 million</td>
</tr>
<tr>
<td>(viii) Others</td>
<td>4.92 million</td>
</tr>
</tbody>
</table>

The above figures are not static, but ever growing. In all civilized countries, the State looks after the handicapped. The rehabilitation services available for the handicapped in India are as follows: (1) medical care facilities (2) education for the blind, deaf and the orthopaedically handicapped (3) vocational training (4) job placement and sheltered workshops (5) pensions, scholarships and allowances for the education and training of the handicapped.

SOCIAL AGENCIES

Social welfare services have always been an integral part of the socio-cultural tradition of India. Soon after Independence, on the basis of a survey made by the Planning Commission, it was estimated that there were 10,000 voluntary organizations in the field of social welfare. Today the number is much greater. The activities are coordinated and assisted by the Ministry of Social Welfare and Women's Affairs. An autonomous Central Social Welfare Board is the main agency of the Ministry for undertaking and implementing programmes for women through the voluntary sector. Activities include welfare, training, health care, provision of women's hostels, as well as legal aid and support to women being exploited by families or employers. A few of the principal agencies are listed below:

1. All India Women's Conference, 6 Bhagwandas Road, New Delhi-110 001
2. National Association of Rural Women, Room No. 9/104, Jamnagar Hutments Block 11, Mansingh Road, New Delhi-110 001
3. National Council of Women, 12 Circular Road, Patna-800 001
4. India Social Institute, Department of Women's Development, 24 Benson Road, Bangalore-560046
5. Centre of Science for Villages, Magan, Sangrahalya, Wardha - 442 001

COMMUNITY SERVICES

Administrative pattern of the country

(1) CENTRE

India is a Union of 29 States and 7 Union territories. Last state Telangana was formed on 2nd June 2014. The Constitution of India came into force on 26 January, 1950. The Union Executive consists of the President, the Vice President, the Prime Minister and the Council of Ministers. Rules of business have been framed under the Constitution.

Indonesia is a sovereign Democratic Republic with a Parliamentary form of government. Sovereignty ultimately rests with the people. The Parliament consists of the President, and the two Houses of Parliament – The Rajya Sabha and the Lok Sabha. The Rajya Sabha consists of 250 indirectly elected members, and the Lok Sabha 544 directly elected members. The main functions of Parliament are to make laws for the country, and to make finances available to the Government. The Parliament is assisted by several committees. The term of the Lok Sabha is 5 years.

(2) STATE

The administrative pattern in the States closely resembles that of the Union. The States executive consists of a Governor, and a council of Ministers with a Chief Minister as its head. The Governor who is the head in each state is appointed by the President for a term of 5 years. The State Legislature consists of Vidhan Sabha (Legislative Assembly) and its members are chosen by direct election. In Some States, there is also an Upper House known as Vidhan Parishad or Legislative Council. The powers of the State Legislature have been defined in the Constitution.

The Union territories (e.g. Puducherry, Andaman and Nicobar) are administered by the President through an Administrator.

(3) LOCAL GOVERNMENT

(a) Urban areas: In big cities, the local Government institution is known as Corporation, and in medium and small towns as Municipal Committee or Council. The Corporations are headed by elected Mayors. The executive power of the Corporation vests in the Commissioner. The Corporation deals with matters concerning public health and sanitation, maintenance of roads, bridges, markets, playgrounds, parks and education. Municipalities are headed by elected Presidents.

(b) Rural areas: The rural areas are governed by the system of Panchayati Raj or democratic decentralization.

Democratic decentralization

In democratic societies, the trend is to distribute power as much as possible to the people themselves so that they may be able to manage their own affairs. The Panchayati Raj in India is nothing but democratic decentralization. It is a 3-tier system of local self-government.

Village level ... Gram Panchayat
Block level ... Panchayat Samiti
District level ... Zilla Parishad

Gram Panchayats are elected by Gram Sabhas consisting of the entire adult population of the village. The panchayat consists of 9 to 15 elected members. The Panchayats are responsible for agricultural production, rural industries, medical relief, mother and child health, maintenance of village roads and streets, tanks and sanitation. It is envisaged that the Panchayat institutions will control everything including primary health centres and local schools. The Panchayat Samiti or Janpad Panchayat federates at the Block level, and the Zilla Parishad at the District level. The Panchayat Raj institutions have their own powers of taxation. For the speedy dispensation of Justice, Nyaya (judicial) Panchayats or village courts have also been established.
LAWS

Laws are rules of the State. They regulate the individual and community behaviour. Some laws come into existence out of the local customs and traditions, e.g., the Hindu marriage Act. There are laws which are enacted by Parliament and State Legislatures. The supreme law of the land is the Constitution which sets out the rights of Government and an individual. Some of the important laws in the field of community health in India are:

(4) The Indian Factories Act, 1948.
(8) The Epidemic Diseases Act, 1897.

COOPERATIVES

Cooperatives are a form of conducting business in society. Profits are distributed after all the costs are paid. The Government has established a system of cooperative societies for helping the farmers to obtain loans for dairy, poultry, and irrigation purposes. There are also other cooperatives such as Consumer Societies in urban and rural areas. There are also District Cooperative Unions and State Cooperative Unions.

EDUCATIONAL SERVICES

Education is one of the fundamental rights of man. The purpose of education is to "socialize" children so that they may imbibe the social values and norms of society and prepare them as useful citizens. Education in India is primarily a responsibility of the State. The Constitution provides for free and compulsory education up to the age of 14 years. The National Policy on Education aims at achieving this goal, and for an investment of 6 per cent of National Income on education. The literacy rate in India for the year 2011 was 74.04 per cent; male literacy rate 82.14 per cent, female literacy rate 65.46 per cent. Education is fundamental to health and health to education.

The Central Government is concerned with the determination of educational standards, scientific and technical education, and research. The Medical Council of India prescribes standards for medical education in the country. There is a Ministry of Education at the Central and State levels. Education is thus an important community service, and the school an important community institution.

RECREATION AND CULTURAL ACTIVITIES

India has a great cultural heritage of dance, drama, music and art. There are 3 National Academies for the promotion of art, music and dance. Besides these, there are State Academies for the promotion of art. The All India Radio with its network of stations and the Television are powerful mass media in the country. India also leads the world in the production of films. The documentary films depict the life, art and culture of people in different regions of the country.

ECONOMICS

The word “economics” literally means “house-keeping”. It deals with the human relationships in the specific context of production, distribution, consumption, ownership of resources, goods and services. Economics and sociology overlap in many areas.

Natural resources of the country

India is rich in natural resources and man-power
(1) Agriculture : Agriculture is the main plank of the Indian economy. It accounts for nearly 44 per cent of the National Income, and provides employment to nearly 70 per cent of India’s population. (2) Forestry : Forests constitute another important basic natural resource of the country. Nearly 19.4 per cent of the total land area of the country is occupied by forests. Forests are a source of timber, bamboo, canes, tendu leaves, gum, resins, tanning materials, rubber, dyes, honey, etc. (3) Fisheries : India has a vast sea-coast. The marine products earn foreign exchange. (4) Minerals : India is richly endowed with minerals, e.g., bauxite, coal, copper, diamond, gold, iron ore, manganese, mica, nickel, etc. (5) Man-power : The greatest natural resource of the country is its man-power. The population of the country is 1,210.1 million (2011). The people of India account for about 16 per cent of the world’s population, while occupying only 2.4 per cent of the world’s land area.

OCCUPATIONS

One of the first questions we ask a stranger or new acquaintance is “What are you doing? or “What is your job?”. Occupation is thus a basis of social differentiation. Some occupations are prestigious (e.g., doctors, judges); others (e.g., manual labour) are not. Occupation also reflects the income of the individual, and his standard of living. The occupational structure in India is as shown in Table 5.

INDUSTRIALIZATION

During the early years of this century, the major industries in India were cotton mill industry, jute industry and coal mining. During recent years, there has been considerable industrial expansion. A number of new industries have come up such as steel, sugar, cement, glass, chemicals, soap, vanaspati, heavy electrical and machine tools, etc.

Industries create new conditions of life and new conditions for adaptation. There is shifting of the population from rural to urban areas. People are removed from the
Health problems in industrialized countries have passed through various evolutionary stages, each characterized by different challenges to public health and personal health care. In the initial stage, infectious diseases, malnutrition, and poor housing were combated by socio-economic improvements in combination with public health measures such as the provision of pure water supply and sewage disposal facilities. As scientific advances were made, broader control of acute bacterial and viral diseases were achieved by means of immunization and chemotherapy as well as increased health care for individuals.

The second evolutionary stage has been dominated by chronic diseases, particularly cardiovascular and cerebrovascular diseases and cancer. Scientific and technological progress has produced a wide array of medical interventions for diagnosis and cure, higher levels of specialization in medical practice, and transfer of much of the care previously rendered in doctor’s clinic to elaborate and expensive hospitals. The cost of health care has risen dramatically.

There is evidence in some industrialized countries of a third stage, which might be described as social and environmental pathology. Threats to health arise not from intrinsic disorders of bodily structure and function, but from environmental hazards related to urban development and exposure to toxic substances, as well as from changes in social behaviour associated with violence, alcohol, and drug abuse of epidemic proportion. Industrialized countries have passed through these three stages over the course of more than a century. Developing countries, on the other hand, face the challenge of coping with all the three stages simultaneously, with just a fraction of the human and material resources available to their industrialized counterparts. Policies must be closely related to overall socio-economic development if countries with limited resources are to achieve the greatest possible benefits in health (46).

ECONOMIC LEVELS

National Income

An important background influence is the size and strength of a country’s economy, which is usually expressed in terms of one of the national aggregates, such as gross national product (GNP) or gross domestic product (GDP). These aggregates measure the total volume of national economic activity at current or constant price. By dividing the GNP or GDP by the total population, one arrives at per capita GNP or GDP, which are common general purpose indicators of national wealth. Per capita GNP may thus serve as a general measure of human welfare – that is, of health in a very broad sense. In practice, many health variables are indeed correlated with per capita GNP or GDP. Countries with a high per capita GNP are predominantly industrially developed, while those with a low one are predominantly agricultural, or developing.

Gross National Income (GNI)

Formerly known as GNP or Gross National Product. It is gross income generated from within the country as also net income received from abroad. It is expressed either “at current prices” i.e., at prices prevailing during the period to which the figure refers, or “at constant prices”; i.e., at prices prevailing during a fixed base period in the past, irrespective of the period to which the figures refers. Thus figures ‘at constant prices’ discount the effect of inflation after the base period and measure the changes in real terms. Figures ‘at current prices’ are naturally influenced by inflation but are more useful for, say, international comparisons for the same period.

For GNI per capita US $, the national currency is converted to current US Dollars using the Work Bank Atlas Method. This involves using a 3 year average of exchange rates (45).

PER CAPITA INCOME

An index of the standard of living of the people is “per capita income”. Per capita income in India is among the lowest in the world. According to recent statistics, the per capita income in India (2012-13) was Rs. 63,749 at current prices.

Gross Domestic Product (GDP)

GDP is gross income generated within a country, i.e., It excludes net income received from abroad.

Net National Product (NNP)

It is the GNP minus the capital we consume (e.g., equipment, machinery, etc.) in the production process. In other words, NNP is the market value of all final goods and services after providing for depreciation.

Net Domestic Product (NDP)

It is the gross domestic product minus the value of depreciation on fixed assets.

GDP at Market Price

It is GDP at factor cost plus indirect taxes minus subsidies.

NNP at Market Price

It is NNP at factor cost plus indirect taxes minus subsidies.

GNP at Market Price

It is GNP at factor cost plus indirect taxes minus subsidies.

Purchasing Power Parity (PPP)

It is defined as the number of units of a country’s currency required to buy the same amount of goods and services in the domestic market as one dollar would buy in the USA. According to the latest calculation of per capita GNI and overall GNP of the World Bank, based on PPP, India’s per capita GNI in 2010 has been estimated at $3560 (PPP). It is the fourth largest country in terms of GNP (PPP) with about $2.5 trillion, preceded by the USA ($9.98 trillion), China (about $5.4 trillion) and Japan ($3.5 trillion) (44).

Gross domestic savings

It is excess of current income over current expenditure.

Poverty

The number of people living in extreme poverty in the world has increased, and was estimated that about...
The health consequences of poverty are severe. The poor die younger and suffer more from disability. They are exposed to greater risk from unhealthy conditions at home and at work. Malnutrition and the legacy of past illness mean that they are more likely to fall ill and slower to recover, especially if they have little access to health care. When a family's breadwinner becomes ill, other members of the household may at first cope by working harder themselves and by reducing consumption, even of food. Both adjustments can harm health of the whole family (48).

The poor are forced into occupations that harm their health, lack of access to health care and education, live shorter life and in general lack access to resources and means to improve their lives. These social and economic aspects of poverty are inextricably linked. Addressing these underlying social factors can enable people to escape poverty. Sound economic policies must go hand-in-hand with addressing the social needs of the poor.

Investments to reduce health risks among poor and provision of insurance against catastrophic health care costs are important elements in a strategy for reducing poverty.

Global Hunger Index (GHI) (50)

The Global Hunger Index (GHI) is a tool designed to comprehensively measure and track hunger globally, by region and country. It highlights successes and failures in hunger reduction. It is calculated each year by the International Food Policy Research Institute.

GHI combines three equally weighted indicators into one index:

1. **Undernourishment** : the proportion of undernourished people as a percentage of the population (reflecting the share of the population with insufficient calorie intake);

2. **Child underweight** : the proportion of children under the age of five who are underweight (that is, have low weight for their age, reflecting wasting, stunted growth, or both), which is one indicator of child undernutrition; and

3. **Child mortality** : the mortality rate of children under the age of five (partially reflecting the fatal synergy of inadequate food intake and unhealthy environments).

The global hunger index is calculated by the following formula:

\[
\text{GHI} = \frac{\text{Proportion of undernourished population (PNU)} + \text{Children under weight (CWU)} + \text{Child mortality in per centage (CM)}}{3}
\]

For India the GHI for the year 2014 is:

\[
\frac{17.0 + 30.7 + 5.6}{3} = 17.8
\]

The calculations result in a 100-point scale on which zero is the best score (no hunger) and 100 the worst, although neither of these extremes is reached in practice. A value of 100 would be reached only if the whole population was undernourished, all children younger than five were underweight, and all children died before their fifth birthday. A value of zero would mean that a country had no undernourished people in the population, no children younger than five who were underweight, and no children who died before their fifth birthday.

Some definitions

1. **Hunger** : distress related to lack of food.

2. **Malnutrition** : an abnormal physiological condition, typically due to eating the wrong amount and/or kinds of foods; encompasses undernutrition and overnutrition.

3. **Undernutrition** : deficiencies in energy, protein, and/or micronutrients

4. **Micronutrient deficiency (also known as hidden hunger)** : a form of undernutrition that occurs when intake or absorption of vitamins and minerals is too low to sustain good health and development in children and normal physical and mental function in adults. Causes include poor diet, disease, or increased micronutrient needs not met during pregnancy and lactation.

5. **Undernourishment** : chronic calorie deficiency, with consumption of less than 1,800 kilocalories a day, the minimum most people need to live a healthy, productive life.

6. **Overnutrition** : excess intake of energy or micronutrients.

**Hidden hunger**

Hidden hunger (micronutrient deficiency) is a form of undernutrition that occurs when intake and absorption of vitamins and minerals (such as zinc, iodine, and iron) are too low to sustain good health and development. Factors that contribute to micronutrient deficiencies include poor diet, increased micronutrient needs during certain life stages, such as pregnancy and lactation, and health problems such as diseases, infections, or parasites.

While clinical signs of hidden hunger, such as night blindness due to vitamin A deficiency and goitre from inadequate iodine intake, become visible once deficiencies become severe, the health and development of a much larger share of the population is affected by less obvious "invisible" effects. That is why micronutrient deficiencies are often referred to as hidden hunger.
